EDITORS' FOREWORD

The picture of Mark Hopkins sitting at one end of a log and a student sitting at the other end, symbolizes to many people the apparent simplicity of education. Yet education today is far more complex than so charming a picture suggests.

Ours is an age of specialists, and it is not surprising that education, too, should have its specialists. We have our experts in test construction and our specialists in curriculum building. We long have had educators who centered their attention on methods of teaching, and even on the methods of teaching a single subject, such as reading, but now we have those who specialize on a single phase of the teaching of reading, for example, remedial reading, and even on one aspect of remedial reading, such as the clinical treatment of the child who has not learned how to read despite his normal or superior intelligence. One has only to consult the catalogue of any major university which has a graduate school of education, or the directory of any state department of education, to see how far we have gone in the subdivision of the study of education into specialties.

Much of the credit for the forward looking changes that have occurred in education in recent years rightfully belongs to the specialists, who have influenced professional thought and practice in many ways. By focusing their efforts on a single aspect of a complex process, they have been able to see problems long unnoticed, and to effect reforms sorely needed. To be sure, the path of educational change has not always been a straight line. More than one proposal which was hailed as an epoch making discovery and applied immediately—sometimes with more enthusiasm than understanding or critical judgment—was subsequently found to be neither a discovery nor an improvement. It is nevertheless true that our specialists have made a significant contribution to modern education and that the future holds the promise of even greater contributions by them.

And yet the image of Mark Hopkins and his student continues to haunt the imagination, for the teacher-pupil relationship remains the fundamental one in all education. To a much greater extent than is sometimes recognized, the contributions of educational research become significant only as they are understood and applied by individual teachers, principals, and superintendents. If teachers and administrators see the total pattern of education, as well as the specific tasks on which they are engaged, they can accelerate the pace of educational progress. By its summary of present achievements, the *ENCYCLOPEDIA OF MODERN EDUCATION* may stimulate the extension of desirable policies and procedures and encourage the further development of education.

Professional educators, however, are not the only ones who have a vital interest in educational principles and practices. Just as the school has become increasingly aware of the world that lies beyond its walls, so has the community taken more and more interest in what goes on at school. Traditionally, education in the United States has always been a matter of public concern; it is significant that the board of education, the body that decides matters of policy, is generally composed of laymen and not of professional educators. For educational advance to be translated from theory into prac-

EDITORS' FOREWORD

tice we need an alert, informed public opinion that is sensitive to the implications of educational theories and that understands the goal towards which the school is striving. Public opinion, however, tends to see the immediate problems rather than the more basic issues. Even today it is only the exceptional parent who views educational problems from a broader point of view than that of the immediate future of his child. Taxpayers' groups, for example, often press for the deletion of specific items from the annual school budget without understanding that the economy may be a wasteful one in the course of years. It is clear, however, that in controversies between the school and the public neither side is always right. The informed layman may sometimes see social and economic implications in an educational program to which teachers and supervisors are not sensitive because of their complete identification with it. Thoughtful public opinion may serve as a corrective to professional judgment. If the *ENCYCLOPEDIA OF MODERN EDUCATION* adds to the understanding which public-spirited citizens have of educational problems, all of us who have helped to prepare the volume will consider our efforts well rewarded.

This volume is intended also for a third group of readers who are neither professional educators nor laymen. They are the psychologists and the sociologists, the pediatricians and the social workers, the legislators and the journalists, and the members of all the other professions which come in frequent contact with the schools' activities. To these colleagues in related fields the *ENCYCLOPEDIA OF MODERN EDUCATION* offers a means of deepening their insight into the problems which confront the schools of today.

One of the first problems in the preparation of an encyclopedia of modern education is the selection of the topics to be included. The master list of the items treated in this volume was prepared only after many listings of educational topics had been analyzed and after the tentative master list had been examined by the members of our advisory board and by many other educators representing specialized fields. The present master list reflects a consensus of informed opinion; it is no hastily prepared record of our editorial intuition. It was often disappointing to omit a given topic, yet the omission of relatively less urgent subjects was necessary in order to assure the adequate treatment of more significant problems. The selection of items was complicated further by the fact that modern education is not an isolated body of facts. It is often difficult to decide where to draw the outer boundaries. There are, for example, no fixed lines of demarcation between general psychology and educational psychology, nor any ready means for determining when educational statistics become more mathematics than education. Confining itself to areas that are clearly within the field of education or that lie in closely related fields, the *ENCYCLOPEDIA OF MODERN EDUCATION* nevertheless reflects the surprising breadth of educational activities. The articles range from as specific an item as the teachers' legal responsibility for accidents occurring in school to as fundamental a question as the role of indoctrination in American education.

In some instances it was possible to increase the scope of the volume by making extensive use of cross references. We were able to refer the reader to the specific article in which a concept or a term is explained and avoid a great number of overlapping articles. Similarly, the practice of appending brief, carefully selected bibliographies to all important articles enabled us to present a concise article that would meet the immediate needs of most readers and to indicate where those who need further information would find it.

EDITORS' FOREWORD

Typical of the problem of the selection of topics was the difficulty experienced in the field of comparative education. An encyclopaedia of modern education should devote considerable attention to the educational practices in other countries. The difficult question is how much attention it should receive. To have included discussions of all the educational systems in the world would have left little room for anything else. Because of the influence that the concept of hemispheric solidarity is exerting on educational thinking, we have included all of the countries in the Americas. We have also treated all of the major countries in the rest of the world and enough of the smaller countries to indicate the variety of educational practices and problems found there. In all such questions of selection we sought the advice of our advisory board and of other competent authorities; for the final decision, however, the editors alone must accept the responsibility.

Another major problem was that of approximating objectivity in a field that is often sharply controversial. In some instances, separate articles were prepared by exponents of different points of view. Thus Dr. W. C. Bagley prepared an article on *THE ESSENTIALISTS* and Dr. W. H. Kilpatrick wrote the article on *PROGRESSIVE EDUCATION*. In other instances, it was possible to present various points of view in the same article. Thus, the article on *PROMOTION* is an objective statement of various theories and practices in promotion.

The typical article stresses neither detailed historical treatment nor the kind of specialized techniques that a research worker has to master. Our major interest lay in the preparation of a volume that would aid the student of education as well as teachers, administrators, and other interested persons to find clear and concise explanations of the basic terms, ideas, and movements of modern education. Our major criteria for judging the articles were: accuracy, clarity, impartiality, conciseness, and helpfulness.

Although the space assigned to an article may be a rough measure of its importance—the article on *INTELLIGENCE* is longer than the article on *CENTRAL TENDENCY*—length, alone, is an inadequate measure of significance. Some concepts are so involved that they must be explained at length if they are to be understood by all. In other instances, we sought to avoid both duplications and serious gaps by treating several related concepts in a single comprehensive article.

By limiting the scope of this volume to modern education, we both simplified and complicated our editorial problems, for the word *modern* has various connotations. The word *modern* does not imply an evaluation. As used in the title, it does not mean *up-to-date* as contrasted with *outmoded*, and it does not imply *progressive* rather than *conservative* or *traditional*. To understand the education of today, one must understand more than merely contemporary education, for educational problems have a background which must be known if they are to be appreciated. On the other hand, much that seems important in the contemporary scene may prove to be relatively trivial within a few years. We have, therefore, tended to stress those phases of our heritage from the past which are most useful in helping us to understand the education of today, and we have emphasized those features of present education which are likely to retain their significance in the future. Thus, our selection of educators whose professional biographies are included in this volume represents no attempt at bestowing the accolade of inclusion in this volume upon those educators who are most active and influential in the contemporary scene, but it does include such

EDITORS' FOREWORD

men as Comenius, Mann, Pestalozzi, and Sarmiento, as well as Dewey, Piaget, Terman, and Thorndike.

How much value an encyclopedia of modern education will have depends largely on its contents, but a great deal depends, too, on the way in which it is used. No book is a substitute for a library. An encyclopedia misses its true function if it appears to contain all the answers to all the questions a reader will ask. An encyclopedia should answer the reader's immediate questions, but more frequently, it should stimulate further questioning and continued reading. The bibliographies which are appended to all of the major articles and to most of the shorter ones are an invitation to the reader to proceed further, an invitation the contributors and the editors hope will be accepted frequently, if not regularly.

There is much that an encyclopedia of modern education can offer. An encyclopedia should present concise, authoritative explanations of the terms, concepts, and practices that are referred to in educational literature. By presenting clear cut and accurate definitions, free from dogma, it should help the student of education to combat the vagueness with which words are often used and it should encourage a greater degree of definiteness in professional discussions. As a reference book, an encyclopedia should clarify the reader's difficulties without necessitating research in a large professional library. It is a great convenience to have a single volume that explains what is meant by the constancy of the Intelligence Quotient as well as what is meant by indoctrination, by the Chicago Plan and by the implications of mental hygiene. Though reading an article in an encyclopedia is never an adequate substitute for reading an authoritative book on that subject, it is often sufficient for the person who has neither the interest nor the time to read a book in answer to every question that comes to mind. In recent years, for example, many people have become curious about the kind of educational system that has helped to shape the Japanese soldier. For most readers, the article on Education in Japan will suffice to explain the part that the inculcation of specific attitudes plays in Japanese education. Similarly an article on teachers' contracts should answer many of the reader's questions without necessitating the reading of a volume in educational law.

An encyclopedia of modern education may also be a useful guide to further professional reading. The many demands that are made on teachers and administrators often lead to a narrowing of reading interests. The teacher who is interested in the new trends in curriculum construction may well begin his study of the problem by reading an encyclopedia article on the curriculum as well as the related articles on such topics as *CORRELATION (CURRICULUM)*, *FUSION*, *INTEGRATION*, *CORE CURRICULUM*, *AREAS OF LIVING*, *BROAD FIELDS CURRICULUM*, *UNIT PLANNING AND TEACHING*, and the like.

Even though one rarely sits down to read an encyclopedia from beginning to end, browsing through it has its own compensations. There is more than passing satisfaction in learning that children who have been deaf from birth may nevertheless be taught how to speak (*DEAF, EDUCATION OF THE*); that the parent has no right to demand that his child attend any particular school, the school board being vested with broad discretion to assign students to such schools as in its judgment may be best (*PARENTS, RIGHTS OF*); that Black Mountain College seeks to achieve the ends of liberal education by extending to students the opportunity of living and working with their professors (*BLACK MOUNTAIN COLLEGE*); that

EDITORS' FOREWORD

gifted university students in the Soviet Union may receive a stipend from the government that is larger than the salary paid some of their teachers (*UNION OF SOCIALIST SOVIET REPUBLICS, EDUCATION IN*); that the properties of the public elementary and secondary schools of the nation are valued at about eight billion dollars (*FINANCE, SCHOOL*); that Sarmiento, the "Horace Mann of South America," returned to his post as superintendent of schools after completing his term of office as president of his country (*SARMIENTO, DOMINGO FAUSTINO*); that the system of Braille now used so widely as a means of enabling the blind to read was developed from a code used by the French Army (*TOUCH READING*); and that legally there are few specified qualifications for membership on the board of education (*BOARD OF EDUCATION*).

Any volume as comprehensive as this must be the product of many minds. It is the contributors who give the volume the merit it has, and it is in anticipation of the aid the *ENCYCLOPEDIA OF MODERN EDUCATION* will give to readers that we thank the authors publicly for their assistance. Since there are almost two hundred contributors, space limitations prohibit our enumerating the ways in which each of them has made this work possible. The initials which appear at the end of each article are those of the writer or writers who prepared it, but we found no convenient way of indicating the names of our contributors and advisers who passed on the article before it was published. That our contributors come from all the major institutions for teacher education in this country, from school systems as well as from colleges and universities, from foreign countries as well as from our own, and from other fields as well as from education, indicates that the progress of education depends on no small group of people or institutions.

We are grateful to the members of the Advisory Board, without whose counsel and guidance our task would have been appreciably more difficult, if not altogether impossible. They have given generously of their time and have helped at every stage from the preparation of the master list to the reviewing of the articles. Their influence can be seen throughout the volume.

The satisfaction of working with our collaborators was not without its sorrows. Professor Frank E. Mankiewicz, who was one of the first members of the Advisory Board, died soon after the inauguration of this project. Since he did not have the opportunity of seeing any of the completed articles, we have not taken the liberty of listing him among the members of the Advisory Board. Our gratitude for his early help and encouragement and our sorrow at his death are none the less real. President R. A. Kent of the University of Louisville (Kentucky) died while the volume was in press. It is unfortunate that President Kent did not live to see his material in its place in the published volume.

Altogether, some two hundred men and women have cooperated in producing this volume, largely because of their faith in the enduring achievements of education and their hope for its future. It is in their name that the editors offer the *ENCYCLOPEDIA OF MODERN EDUCATION* to their professional colleagues and to the growing number of laymen who appreciate their stake in modern education.

A. Q.—See EDUCATIONAL AGE.

ABILITIES, CORRELATION OF—See SCHOLASTIC ABILITY.

ABILITY GROUPING—See CLASSIFICATION OF STUDENTS.

ABILITY, SPECIAL — See SPECIAL ABILITY.

ABNORMAL CHILD—See ATYPICAL CHILD; EXCEPTIONAL CHILD.

ABNORMALITY. *Abnormality*, in psychological language, has almost assumed synonymy with *atypicality*. (See ATYPICAL CHILD.) The average behavior or attitude or ability is defined as the norm (*q.v.*). By definition, 50% of the population is expected to show abilities and characteristics above and 50%, below the median. Behavior is considered abnormal only when it is so far away from the norm that relatively few other persons exhibit that degree of it. This psychological and statistical use of the words norm, normal, and abnormal, carries no connotation of goodness or badness. The judgment of whether the abnormal is good or bad must be made separately. Sometimes abnormality in either direction is considered bad, as in traits like weight, blood-pressure, stinginess-generosity, or aggression-submission. Sometimes great value is set upon abnormality in one direction, as upon high intelligence or high musical ability. In traits related to mental health, atypicality in either direction means maladjustment; thus, both extreme conceit and extreme modesty may lead to difficulties in effecting personal and social adjustment.

B.B.F.

ABREACTION. The process of reliving earlier life experiences which have led to mental conflicts. It is effected in a psychotherapeutic situation (*i.e.*, treatment interview between therapist and patient), and involves the recounting of the earlier life ex-

perience together with an expression of the accompanying or final emotion. In this manner the emotion attached to the original events is discharged and loses its capacity to produce distorted or pathological attitudes and reactions. Its value is largely dependent upon the skill of the therapist. Abreaction is, therefore, no simple process to be set in motion merely by the teacher's inviting the pupil to relax and to speak freely. It is a technical phase of therapy that should be employed only by those who have the requisite psychiatric training and experience.

ACADEMIC COSTUME. Academic costume refers to the caps, gowns, and hoods worn by students, faculty members, and school officials. Originally the use of academic costume was limited to institutions of higher education, though it is now used in many secondary schools. The long, looseflowing gown, usually black, is a survival of the clerical gown of the middle ages, when all scholars were cleric. The hood is a modification of the Friar's hood, which was attached to the robe and was at first intended as a covering for the head. Academic costume was first used at Cambridge University in 1284. In England today each university has its own style of robe and hood, and each department in the same university has its own style of robe.

The movement to use academic costume in the United States, sponsored by students, came in about 1880. Caps and gowns were worn by the seniors at Williams in 1883, and by the seniors at Wellesley in 1884. Bryn Mawr faculty and seniors adopted academic costume in 1885. By 1890 the custom was general. Because of diversity of costumes, a commission, appointed in 1893, drew up a code of academic dress which is now followed

in the United States by all colleges with the exception of a few which still follow the English costumes. The Intercollegiate College Bureau of Academic Costume, Albany, New York, has a register of all official college colors used on academic costumes. The color of the robe is black; the style of the robe differs for the various degrees.

Intercollegiate System of United States:

Gowns. Undergraduate—black, no hood, rounded or pointed sleeve, open or closed.

Bachelor's—black, with hood, long pointed sleeve, open or closed.

Master's—black, preferably silk, long closed sleeve, with slit near upper part for arm opening, with hood.

Doctor's—black, preferably silk, with round bell sleeve; gown faced down front and barred on sleeves with black velvet or velvet wholly or in part of the degree color, with hood.

Hoods. Same material as gown; different shapes for bachelor's, master's, and doctor's; lined with silk of the official colors of the institution; trimmed with velvet of the color indicating the degree.

Degree colors. Arts and Letters, white; Theology, scarlet; Laws, purple; Philosophy, blue; Science, gold-brown; Fine Arts, brown; Medicine, green; Music, pink; Oratory, silver-gray; English, orange; Pharmacy, olive; Dentistry, lilac; Vet. Sc. gray; Forestry, russett; Library Science, lemon; Pedagogy, light blue; Commerce (inc. Accounting), drab.

ACADEMIC FREEDOM. The meaning of the term *academic freedom* varies, depending on whether the reference is to institutions of learning or to teachers, and depending further on the grade or level of the institution to which the term is applied.

In universities and colleges, academic freedom implies for teachers freedom to engage in research and to publish the results of such research, subject only to the competent performance of their academic duties. The principle of academic freedom asserts the teacher's freedom to discuss his subject in the classroom and to present his views on

controversial issues, provided that he accords similar treatment to views other than his own, and provided further that he does not introduce controversial matter that lies outside the field of his specialization. A like freedom is claimed for teachers in the secondary and elementary schools, but there is added a further limitation which requires of teachers in such schools a respect for the feelings of the community and particularly of the parents directly concerned.

Customarily, pronouncements on academic freedom comprise a clause vouchsafing for the teacher the exercise of the same freedom of expression and action outside the classroom as is the common right of all citizens. These assertions of the fact that the teacher does not forfeit his civil rights by virtue of his membership in the profession are a repeated reminder that communities and public officials have not hesitated to impose special restraints and regulations on the extra-mural or even private behavior of teachers. Such special restrictions, while not as universally imposed as they were formerly, are still applied in many school communities.

The teachers who are usually subject to such controls are those in elementary and secondary schools, but college and university teachers are by no means secure against reprisals if their conduct outside the classroom, legal though it be, proves offensive to powerful elements in the community. Indeed, one of the most flagrant denials of academic freedom in recent years was a case involving the teaching of mathematical logic by the world's most distinguished exponent of the study.

It is generally admitted that religious institutions or proprietary institutions which are organized for special purposes may impose limitations of academic freedom on the teacher, provided such restrictions are clearly stated as a condition governing the acceptance of appointment.

The principles of academic freedom derive their importance from the fact that recognition or denial of the teacher's right to certain freedoms vitally affects not only the students but society itself. If schools, colleges, and universities were established for the sole purpose of perpetuating the achievements of the past, there would be fewer attempts to impose restraints on those who teach. But schools, and more especially schools of university and

collegiate rank, carry an added responsibility. On them rests also the obligation of testing the validity of facts, of reassessing values, of inquiring anew into problems still unsolved, and of announcing their findings. These activities which by their very nature are a challenge to the *status quo* in the sciences and in the social arts inevitably involve teachers and schools in controversies with those who have a share in their support or governance. The teacher is a citizen; but he is also an instructor of students less mature than himself. By knowledge, experience, and the prestige of his status, he enjoys advantages which if abused may deprive students of their rights to well-informed and unbiased instruction.

The teacher whose freedom is likely to be challenged is not the free-lance scholar who renders a service of teaching outside of institutional auspices. In almost all cases he is a member of the faculty of an institution which assumes responsibilities for its students. In these obligations the teacher shares when he accepts appointment, and in doing so he is expected to accede to a curtailment of his right to complete independence of action. The question of how much curtailment is valid lies close to the heart of the issue in most conflicts involving the principles of academic freedom.

No subject of instruction, and no level of school is entirely secure against the negation of the teacher's right to freedom of teaching. While the difficulties arise most frequently in the social and biological sciences, teachers of philosophy, literature, and religion are often the targets of official and unofficial censure. Neither are the restraints confined to direct instruction. They may involve dictation or censorship of textbooks, the control of the curriculum, or the arbitrary imposition of instructional procedures. In practically all categories, it may be added, cases have been recorded in which teachers have themselves been found guilty of abusing the rights of free teaching.

Concepts of academic freedom have developed traditionally not only in relation to the rights of teachers, but also in relation to the rights of students. Since, however, any principles about student rights must derive from theories about the purpose of the educative process and about the place of the learner

in that process, there have not been developed any formulations about the freedom of the learner that are as generally accepted as are the definitions of freedom of teaching. Each school of educational thought evolves its own conclusions about the freedom to be accorded to the learner. These it derives from its basic social and psychologic commitments. The term academic freedom has tended therefore to become exclusively associated with teachers' rights and with the freedom claimed by schools and universities to seek and disseminate knowledge.

Prior to the publication of *The Origin of Species*, it was generally assumed by teachers as well as laymen that the chief function of colleges and universities was the dissemination of existing knowledge. The issues that divided university men had been few in number and, with one notable exception, had not been of a kind to test the validity of any pronouncement on academic freedom. That exception was the question of Abolition. Its espousal led to four or five dismissals in American colleges and fostered wide discussions in university circles about the limits of academic freedom.

Further discussion of the issues involved in the rights of free inquiry and free teaching was stimulated by the controversy which developed around the theory of evolution. The denominational communities under whose auspices most American colleges had been founded saw the new biology as a threat aimed at the very life of the institutions which they were supporting. While it is generally assumed that science emerged triumphant in this bitterly contested battle, the Scopes trial in Tennessee (1925) serves as a dramatic reminder that less than twenty years ago the right of teachers to teach the truth as they understand it was still being effectively challenged and denied.

Teachers were dismissed from their posts in universities, colleges, secondary and elementary schools during World War I for entertaining views too pacifistic to meet with the approval of school administrators or boards of trustees. In more recent years a school ordinance enjoined teachers in the District of Columbia from making any reference to the form of government adopted by the Union of Socialist Soviet Republics.

These and similar instances have stimu-

lated a number of organizations to exercise a special vigilance over schools with a view to contesting any and all infringements of academic freedom. The American Association of University Professors, The American Federation of Teachers, and The Civil Liberties Union have devoted themselves persistently to the defense of teaching.

The beginnings of academic freedom may be traced to the Middle Ages when popes, emperors, and kings, in the effort to induce university bodies to establish themselves within the realm, guaranteed them their independence from civil jurisdiction. Thus Frederick I, or 'Barbarossa,' granted the students of Bologna courts of their own and complete autonomy in the management of their affairs. Similar grants were made by Philip Augustus to the University of Paris and by Rupert I to Heidelberg.

Not, however, until centuries after the independence of universities in the regulation of their own affairs had been acknowledged did the rights of the teacher to freedom of inquiry and expression receive any recognition. It was in Germany, early in the eighteenth century, that the claims to *Lehrfreiheit*, or academic freedom as we now understand it were first asserted and subsequently approved. Göttingen, founded in 1732, was among the first universities to extend such freedom to its faculty.

The second half of the eighteenth and the first half of the nineteenth centuries witnessed the extension of these rights to universities both in Germany and other countries. "This institution," wrote Thomas Jefferson at the founding of the University of Virginia (1819), "will be based upon the illimitable freedom of the human mind. For here we are not afraid to follow truth, wherever it may lead, nor to tolerate error as long as reason is left free to combat it." It is easy to attach to Jefferson's pronouncement and to similar declarations made more than a century ago greater significance than they merit. The true measure of their strength remained still to be tested during the second half of the nineteenth century when, in America as elsewhere, controversies developed over issues which divided men into bitterly opposing camps. ACADEMY. The term *academy* has appeared at various times in the history of education. Plato first used it as the name of the school he founded in 386 B.C. This was a cooperative venture of teachers and students for the teaching and learning of philosophy, mathematics and science. It became the model for other schools designed to offer a "philosophical solution of the problem of life". During the fifteenth century academies designed to promote literary studies were founded in all important Italian cities. These had many of the characteristics of their Athenian predecessors.

The name again appeared in England during the seventeenth century, applied to the school founded by John Milton to provide a classical education concerned more with substance than with form, a revolt against the formal humanistic school.

The first academy in the United States was founded in Philadelphia in 1751 by Benjamin Franklin. This later became the University of Pennsylvania. The academy movement spread rapidly until during the first half of the nineteenth century this form of semi-private school was the dominant type of secondary education in this country. It all but replaced the earlier Latin Grammar School and became the precursor of the American public high school. More than 6,000 schools enrolling over 263,000 pupils taught by at least 12,000 teachers existed by 1850.

The academy differed from the Latin Grammar school in certain basic respects. (1) It was not associated closely with the colleges and was therefore not primarily college preparatory. (2) Its curriculum included the more useful subjects of the day, in addition to mathematics, science, modern languages and history. (3) It provided a "rounding out" education for those who had completed the English education of the common school. (4) It gave general preparation for business

life and the rising professions. (5) Building on top of the education of the common school rather than parallel with it as was the case with the Latin Grammar School, it served as an introduction to the more democratic high school of today.

The academy in the United States was therefore an expression of the philosophy of realism applied to the education of youth and served as the transition from the traditional classical school dominated by the colleges to the American public high school which is much more an expression of the wishes and needs of the people. By the beginning of the twentieth century the academy had been almost entirely replaced by the public high school. (See SECONDARY EDUCATION.)

The few which remain are private schools and frequently college preparatory in nature. A number have been converted into private military schools.

ACCREDITING. Accrediting is the improving by a standardizing association of an educational institution of any grade because it satisfies the requirements set for approval by that association.

The act of accrediting various educational institutions—public and private or elementary, secondary, and higher—was not undertaken seriously until the latter part of the nineteenth century. Four problems brought accrediting to the fore. First, what should be the requirements for entrance to freshman work in college? If high school graduation was to be accepted, what standards, if any, should be met by high schools that hope to have their graduates accepted? Second, in-

stitutions of higher education needed help in determining whether given individuals should be admitted to graduate study. Third, each of the 48 states faced the problem of securing satisfactory teachers to serve in the elementary and secondary schools of the state. Fourth, each state had a responsibility for licensing in the various professions—law and medicine, for example.

The accrediting agencies include state boards or departments of education, state universities, intercollegiate standing committees, and state college associations within the various states. There are also regional groups composed of representatives from colleges and secondary schools organized in the New England States, the Middle Atlantic States, the Southern States, the North Central States, the Northwestern States, and the Western States. These organizations accredit both secondary schools and colleges within their respective areas. There are professional organizations such as those in law and medicine that accredit institutions in their particular fields.

The process of accrediting in its complete sense involves three activities. (1) Certain minimum standards are prescribed that the institutions desiring accreditation must meet. (2) Institutions must be visited to determine whether they are maintaining such minimum standards. (3) A list of all institutions meeting these standards is then published. Not all accrediting agencies perform all these functions; some perform only one or two of them.

The accrediting of educational institutions, as it is carried on in the United States, is unknown in countries where education is controlled by the central government. But with education locally controlled, as it is in this country, some plan is essential whereby the people may know the standing of the various elementary, secondary, higher, and professional schools. The multiplicity of accrediting agencies has created many problems, and educational institutions have often suffered from their exacting demands. A recent investigation by the Office of Education recommended, after months of study, that the work of accrediting be changed "in the direction of placing greater responsibilities upon appropriate agencies in the several states."

The early work of accrediting was based

upon certain quantitative measures through which an appraisal was made of an institution's physical plant, its monetary support, its teaching staff, and its equipment. If the institution failed to meet these quantitative standards, it was not accredited. Beginning in 1929 a shift was made in the direction of qualitative standards. An institution was to "be judged in terms of the purposes it seeks to serve." There was also a tendency to judge in terms of the "total pattern" of a given school; if a school was low on financial support but had an unusually strong teaching staff, it might well be judged an effective institution. This change does not seek less quantitative data in arriving at a decision as to accrediting; it demands far more. It takes these more extensive data and arrives at a picture of the institution's effectiveness rather than judge the school upon the basis of a few criteria that are easily checked.

In line with this change the new "evaluative criteria" being applied to secondary schools furnishes a more intelligent basis for accrediting the state's secondary schools. (See EVALUATION.) These criteria involve an analysis of the school's curriculum, pupil activities, library, guidance activities, instruction, outcomes, staff, plant, and general administration. Standards are devised for each of the categories. The school being studied is appraised in the light of how well it seems to be doing its job despite lacks in one or more of these categories. It is being recognized, likewise, that the mere accrediting of a school is only the initial step in the complete process of helping the school to make changes that will make it an even more effective educational institution. A.O.H.

ACHIEVEMENT AGE—See EDUCATIONAL AGE.

ACHIEVEMENT QUOTIENT — See EDUCATIONAL AGE.

ACHIEVEMENT TESTS. Tests designed primarily to measure the attainment of an individual or group of individuals in a school subject or activity, as in arithmetic, reading, or history. Most published achievement tests are standardized tests (*q.v.*). An achievement test may be either a single test to measure the ability in a single subject or a *battery of tests*, i.e., a number of tests ordinarily administered as a unit but designed to measure achievement in several different subject matter fields (e.g., Metropolitan Achievement Tests). The *survey test* is one designed to measure the average achievement of large age or grade groups. Survey tests, if used solely for group measurement, need not meet the high standards of reliability set for measures of individual achievement.

Achievement tests usually consist of a great many objective type questions (See OBJECTIVE TESTS AND EXAMINATIONS) to facilitate scoring. This emphasis on objective-type questions has been criticized on the ground that they tend to stress factual learning and the acquisition of specific skills more than the appreciative and the interpretative aspects of learning. The use of objective questions is not always feasible, as, for example, when we wish to measure the pupil's attainment in penmanship, where a *quality scale* is more appropriate. A quality scale is a device for obtaining a rating of the degree of excellence of a given sample of work. Specimens of drawing, penmanship, or composition are evaluated by a group of judges, assigned a value from zero to one hundred, and arranged on a chart in terms of order of merit; a rating may then be obtained for a given specimen of work by matching it with the one on the scale which it most closely resembles.

The scores on achievement tests may be interpreted in terms of their norms (*q.v.*) or used as the basis for converted scores (*q.v.*).

The advantages and limitations of standardized achievement tests are similar to those of standardized tests (*q.v.*). J.J.

C. C. ROSS, *Measurement in Today's Schools* (Prentice-Hall, New York, 1941).

ACQUISITIVENESS. *Acquisitiveness* has been listed by numerous psychologists in the past as a human instinct or inherited tendency. While lower animals such as squirrels may give evidence of collecting and hoarding without example or teaching, the acquisitiveness of children and adults, however, is best understood by a consideration of the environmental influences affecting them and the interests that they develop through social contact. Anthropologists have contributed to the criticism of the "instinct theory" of human behavior, as applied to such traits as acquisitiveness, by showing how greatly acquisitive behavior varies in different societies, including complete common ownership of property, comparative disregard of property, and extreme emphasis upon individual ownership. It is no doubt true that personality development is enhanced through the acquisition of objects, as well as of knowledge and of friends, but the specific forms that acquisitive behavior will take are various and modifiable. That a person wants more of the same thing is not so important as what it is that he wants more of, how he uses the "more" that he has acquired, and to what lengths he will go to acquire this abundance.

The attempt often has been made to use children's collections as an index of their interests. This has proved to be a more complex task than the mere naming of the collection. The child's attitude toward his collection and his "gang's" attitude toward it must also be taken into account. Sometimes the collection is the manifestation of an intellectual or æsthetic interest in the field. In this case much care and study go into the activity, and discrimination as to what should be acquired and preserved is constantly in evidence. At other times a certain kind of collection is the popular fad. The children both compete and share with each other. The collections act as a medium of social interchange. As with all fads, this type of collection may lose appeal or cease suddenly. Then the collected objects are usually dis-

carded. Collections may also serve to bolster the status feeling of the individual, and are often made in those very areas where there is the greatest feeling of inferiority. This is more true of adults than of children, since possessions do not have the prestige value for children that they have for the adults in our society.

Many teachers have tried to use the "collecting tendency" of children to arouse interest and learning in some school subject. Studies show, however, that if left to himself a child may not collect anything for years. The teacher cannot depend on any "desire to collect" to guarantee that successful learning outcomes will be produced by the technique of requiring the children to bring in materials (such as postcards, news clippings, magazine articles, object samples, etc.) either for individual collections or for a class collection. The degree of learning the children get by means of this technique depends on how the teacher uses it, not on any hypothetical general acquisitive tendency.

ACTIVISM. The importance of activity as part of the learning process has long been recognized. What that part is, however, and what its relative importance is, are questions around which considerable controversy has raged. The primary difficulty seems to stem from the problem of the proper relation of knowing and doing, a problem derived from the old mind-body enigma.

According to Aristotle and later the Scholastics, learning involved both physical or sensory activity and mental or rational activity. Of the two, the latter was held in higher regard because it operated as a check on the former and was the avenue through which the general or universal in experience was realized. Furthermore, rational activity was conceived to be activity in its purest form and hence the highest good. In the course of time this greater emphasis on the intellectual aspects of learning turned into an almost exclusive emphasis. Education became excessively bookish and verbal. In due course this disproportionate emphasis led to protest

and finally to reaction.

It was the educational reformers of the post-renaissance period, especially Comenius (*q.v.*), who were the first to redirect attention to sensory and muscular activity as a much neglected phase of education. Comenius' epoch-making *Orbis Pictus* made the initial inroad into verbalism by the introduction of pictures into textbooks, thus appealing to vision as well as intellection. The naturalists, primarily Rousseau (*q.v.*), reacting strongly against the current rationalism (*q.v.*), found worth in an education providing for free exercise of physical powers, the sentiments as well as the limbs and organs of the body. Pestalozzi (*q.v.*) was among the first to fashion a practical method whereby this activistic theory could be employed in the schoolroom. His principle of "object instruction" was extended by Fellenberg to manual labor and later through the *sloyd* movement to manual training in general. In the idealism of Froebel (*q.v.*) activism took the form of play. The movement was reinforced and expanded by scientific psychologies whose analysis of child nature revealed instincts and emotions as the basic drives to conduct. With pragmatists like Dewey (*q.v.*), activity is coincident to investigation and an opportunity to try out one's ideas on things to see how means can be adapted to ends. Most recently activism has been promoted by a psychoanalytic group on the theory that expression rather than repression is the educational avenue to mental health.

Underlying these historical assertions of activism in education lie two fairly distinct theories. The one theory proceeds from the premise that it is the biological or psychological character of human nature to be dynamic, growing, active. Hence the curriculum must be composed of activities so that these potentialities for action may be actualized. In this direction lie sense training, discipline of the faculties, busy work, "self-activity" of the Froebelian kindergarten, expressionism, perfecting one's abilities, and growth as its own end. The exercise or training of the activity itself is the end of the educative process. The content is relatively unimportant. The obvious though not necessary danger here is formalism.

The other theory looks on activity, not as an end, but as a means. Activities, both phys-

ical and mental, are purposefully undertaken to gain ends and to see what consequences flow therefrom. In this sense the word "activity" has come to have an almost technical meaning. Thus, a situation in which a child feels the need for making an adjustment, sizes up his problem, thinks out a solution, and actively rearranges the internal and external circumstances of his life to bring his solution about, has in some quarters come to be known as an "activity." Such learning situations also go by the titles of "unit," "project," (*qq.v.*), "problem," and even "experience." Situations vary as to how much activity will be inner and mental and how much overt and physical, but none will be exclusively either.

There are also secondary aspects of activism which will be seen to take their further significance from whichever of the preceding theories one subscribes to. Thus, interest, spontaneity, and freedom have all been identified as concomitants of learning by doing. It makes a vast difference, for instance, whether freedom is advocated as the necessary basis for the release of any or all potential activities of which one is capable or whether it is the prerequisite for experiment and inquiry. It is the difference between a freedom bordering on boisterousness or even license and a freedom definitely under the control of purpose. (See also ACTIVITY PROGRAM.)

G. G. SCHOENCHEN, *The Activity School* (Longmans, Green and Co., New York, 1940).

ACTIVITY PROGRAM. The Activity Program has had many definitions. In the Thirty-third Yearbook, Part II, of the National Society for the Study of Education forty-two definitions by eminent authorities are cited, ranging from "*a device*" for teaching prescribed subject matter on the basis of children's interests and experiences to a disregard for formal subject matter and the concept of "*a curriculum worked out 'on the spot' by boys and girls under the guidance of teachers.*" To some it means *experiential learning*; to others, *unit organization of work, study or experience*; to still others, *a series of projects*. The activities implied cover a wide range of physical, manual, social, or intellectual experiences.

Perhaps the best single definition is the

ACTIVITY PROGRAM

one reported in the Survey by the New York State Department of Education of the six year experiment with the Activity Program in the elementary schools of New York City from 1935 to 1941:

"As conceived in the New York City experiment the development of an activity program was primarily an effort to shift the emphasis of teaching in the elementary school from subject matter to the child. It was an attempt to make the child an active participant rather than a passive recipient in the educational process.

"The Activity Program placed special emphasis upon the development in children of self-control, critical thinking, creative expression, and desirable social relationships. These were to be attained in part through children's participation in planning their work, through learning by actual experience, and helping to keep records and to evaluate work done. It emphasized adapting materials and methods to the needs and abilities of individual pupils; the wider use in the school program of opportunities for creative work in art, music, dramatics, and construction; and the creation of school and classroom atmosphere conducive to democratic living, and of friendly, active, cooperative relations between school, home and community."

Activities referred to in this and in other definitions are more overt in the primary school, and tend to become more identified with research around organized courses of study or large community enterprises in the secondary school.

The variety of terminology used in defining the Activity Program and in describing its essential characteristics has been confusing and has led to much unfavorable criticism. The Activity Program has been conceived by some as 'loose discipline,' 'absence of organized content,' 'child domination,' artificial and unrelated 'projects,' 'boondoggling' of orange crates and disregard for authority, absorption in the 'here and now,' and failure to transmit the 'cultural heritage of the race.'

These misconceptions have arisen from failure to understand the educational shortcomings which the Activity Program attempts to correct as well as from observation of well-intentioned but uninformed applications of the Activity Program by misguided en-

thusiasts.

1. The Activity Program represents a *series of reactions* against the 'lock step' in education, teacher domination, regimentation of discipline and instruction, stratified subject matter, meaningless verbalism, reliance on repetitive drill and memorization, and other objectionable forms of traditional practice. Some of these reactions were so violent as to lead to absurd extremes.

2. The Activity Program represents an *attempt* to integrate into a well organized pattern the best modern concepts of elementary education. Hence the varied emphases. In the evolution of elementary education many concepts have been developed which have been displaced by subsequent theories. For example, the Gestalt theory of learning has largely supplanted the more limited conceptions of transfer of training and specific responses to specific situations.

3. The Activity Program is regarded as education for citizenship in a democracy. As such it recognizes and provides for the potentialities and needs of the individual as well as for his relations and obligations to society. It therefore sets up a pattern which rejects autocratic control in favor of gradually increasing *self-control for individuals* and *self-government for groups*. In the light of its major objective, training for democracy is susceptible of as many variations as the concept of democracy itself.

4. The Activity Program is a manifestation of the influence of the Scientific Movement in education. Emphasis is placed on experiential learning, on experimentation, and on child-study rather than on a pattern of passive, receptive learning through formal recitation.

All learning involves activity of some kind. Even passive listening or re-citing requires some activity. The following scale patterned after that of Leo J. Brueckner (33rd Year-book, Part II, National Society for the Study of Education, Appendix I, pp. 212-214) indicates an ascending order of learning activities characteristic of various activity programs:

1. Lowest level. No systematic program of activities. Whatever activity is used is regarded as a *device* to motivate learning or as an *application* of something assumed to be already learned. Deferred values are regarded as more important than immediate values. "You will need this when you grow up."

ACTIVITY PROGRAM

2. On the next level the activities are largely unrelated and incidental. They are *extra-curricular*, like clubs, safety patrols, school papers, or pageants. Occasionally some regular school time is allowed for this type of activity. Participation in it has some recognizable values, aside from subject matter mastery.

3. At this level activities are isolated *projects* conducted during school hours or they are related intra-curricula activities like setting up a post office or a store or reproducing in miniature an Indian village or a market. The purpose is largely to *enrich* or *vitalize* the work planned by the teacher. Voluntary participation and individual initiative and choice are often present, but not especially planned for or stressed. Formal subject matter still dominates.

4. On this level the pupil is thought to learn most completely if the work of the school is organized into *units* dealing with activities as nearly as possible like those in life outside of school. Subject matter organization is still retained. The selection of units and activities is still made largely by the teacher. There is considerable correlation of subject matter. The outcomes tend to be stated in terms of pupil growth rather than mastery of subject matter 'set out in advance to be learned.' There is some opportunity for pupils to make or to discuss suggestions or to select from activities recommended by the teacher. The course of study lists carefully described activities that suggest to the teacher ways in which the agreed objectives of separate subjects may be achieved. The teacher provides a stimulating environment and guides children's activities. The class 'covers' a course of study but community affairs and pupil interests are used advantageously as 'approaches' to the units of work. There is some provision for pupil planning, participating, discussing, executing, and evaluating within limits set up by the teacher. Subject matter and skills not naturally achieved in connection with the unit of work are taught and drilled separately.

5. At this level traditional *subject matter* is *disregarded* as unlikelike and unnatural. The work of the classroom is organized about projects and activities of immediate and challenging interest to the group. The course of study is a guide, not a prescription. The time schedule is flexible. There is a school library

and classrooms have library corners with ample provision for free reading and well-organized reference and source materials, where, with guidance, pupils may readily locate information about the problems and subjects they are studying. School museums, community museums, and public libraries arrange for exchange of materials with the school for research or demonstration purposes. The function of the teacher is to guide the activities of the pupils into educational channels. The teacher devotes much of her effort to enriching her own experience and broadening her point of view and her intellectual horizons. She helps pupils to overcome their difficulties, to evaluate their performance and achievement, and to enrich their understandings and appreciations without overtly dominating their activities and purposes. Pupils learn to recognize and attack actual problems of life under the guidance of the teacher. They acquire technics for solving them and the will to solve them. Education is thought of, not only as the plan by which society endeavors to transmit the social heritage, but also as the process by which the individuals and groups learn to take part in the "continual reconstruction of experiences to higher levels."

The elements of the Activity Program are not new. Before schools were established experiential learning in social situations was almost the only way of learning. One sees in the program reminders of the influence of the Renaissance with its emphasis on the joy of living and learning as typified by Vittorino da Feltre; of the Reformation as a revolt against passivity, conformity, and authoritarianism; of the social and natural approach of the Realists with their resistance to formal instruction, book learning, and verbalism and their emphasis on participation and experiences; of the Scientific Movement with emphasis on induction, experimentation, and validation; of the democratic movement with its esteem for the individual, the rights of man, and the brotherhood of the human race. One recognizes the influence of Comenius's stress on the appeal to the senses through objective aids; of Rousseau's concern for child-study, natural development, and self-expression; of Froebel's vision of the kindergarten—"the garden of children" and of the place of play, self-activity, and growth; of Pestalozzi's realization of the

ACTIVITY PROGRAM

possibilities of object teaching, of manual training, and of industrial and agricultural art; of Herbart's insistence on motivation, correlation, and character training; of the emphasis by Dewey and Kilpatrick on adjusting learning experiences to the learner, providing conditions and challenges to stimulate growth in natural situations, analyzing the process of thinking, reconstructing experiences on higher levels, and bringing education out of the classroom into the laboratory, the library, the studio, and the world outside the school.

What is new about the activity program in its best forms is the integration of all these influences into a constructive program of education and child development in a social milieu. The program is thus a philosophy of education, a curriculum, and a methodology. As a philosophy it is concerned with the objectives and principles of education. As a curriculum it is concerned with a pattern of democratic living and the experiences and activities inside and outside the school including subject matter and skills through which these objectives can best be realized. As a methodology it is concerned with working conditions, challenges, motivations, teacher knowledge of pupils and their environment and how they learn, and the ways in which optimum pupil participation in the planned curriculum of the school in typical situations may be achieved. As a part of its concern for the needs of individual pupils it includes the practice of remedial procedures with those pupils who fail to acquire learning as a result of significant experiences.

The Activity Program tends to supplant the formal recitation and repetitive drill of the traditional curriculum. In a good activity program these are retained to a degree but the more overt and characteristic procedures are: (1) *discussion, conference, pooling* ideas and arriving at plans or decisions; (2) *trips*, actual or vicarious through motion pictures, stereopticon slides, or other objective aids in which the children observe and handle real objects in real situations, (3) *research*, in which children explore problems raised by themselves through interviews, inquiries, or extensive critical reading, (4) *dramatic play* or dramatization, in which children 'make believe' or enact original or studied episodes and plays and identify themselves more closely with people

and situations important to them, (5) *construction*, in which children reproduce, usually in miniature, what they are studying, (6) *pictorial or graphic representation* as another way of interpreting and organizing what they are learning, (7) *sharing experiences and findings* with each other, with other classes, with assembly groups, or with the community, (8) *culminations*, in which projects or units of study or work are brought to a significant termination in the form of an exhibit, a program, a pageant, or a demonstration, (9) *evaluation and fixation*, in which through reviews, tests, check-ups, drill, and other devices pupils fix the information or skills which they regard as important or necessary.

Many of these features are observable in the work of good teachers in any school, but the emphasis in the activity program is consistently on individual and social growth through guided challenging experiences.

The introduction of the Activity Program in a school previously run along traditional lines presents many difficulties because of the demands of long established courses of study, lack of teacher training in newer practices, unsuitable equipment, and the characteristic inertia and resistance of traditional teachers and administrators. These difficulties are accentuated when an entire school system is faced with such a drastic change from traditional subject-matter emphasis to the Activity Program. The introduction of the Activity Program into the elementary schools of New York City is of particular significance because of the light it sheds on the problems involved in such a transition and their possible solutions. Before introducing the Activity Program into all schools, New York City conducted a six-year experiment in seventy selected schools, typical of all the local communities and school organizations. The experiment included 80,000 children and 2,500 teachers, a typical school population as large and varied as the total school enrollment of many a large city.

Near the close of the experiment the State Department of Education, on invitation, made an extensive survey of the Activity Program and recommended its gradual extension into all public elementary schools. Acting on these recommendations, the Board of Superintendents approved a modified activity program for general adoption in November,

ACTIVITY PROGRAM

1941. Beginning February 1, 1942, it became the official program for all elementary schools. As a general policy greatest emphasis is being placed on the lowest grades at first. As the children advance at promotion time, they are continued on the program. It will take probably eight years to complete the transition from the former program.

The following quotation from the *Survey of the Activity Program in the New York Elementary Schools* by the State Department of Education (pp. 170-172) indicates the demonstrated values of the Activity Program:

"In reviewing its findings, the Survey would emphasize that the chief contributions of the activity program as conceived and developed in the New York City Curriculum Experiment have been to improve pupils' attitudes, their ability to think and their social behavior. Nor have these gains been accompanied, as some feared, by significant loss in mastery of fundamental knowledge and skills. While the balance in favor of the activity program is small, there is a very real possibility of increasing that margin of difference through improving the theory and practice of the activity program. When considered in terms of a million children this gain is a matter of great moment to the people of the city and the State."

The following recommendations were made in the report of the Survey:

"Continue the emphasis on the development of the personal qualities of the individual pupil such as the power of self-discipline, self-confidence or poise, ability to work with others, lack of subservience and willingness to assume responsibility.

"Continue the emphasis on development of civic attitudes and understanding of socio-economic questions within the range of the child's experience and understanding.

"Continue the excellent work already evinced in cultivating critical thinking and children's resourcefulness in working on their own initiative.

"Give more attention to the theory and practice of discovering and cultivating the creative talents of children as expressed in writing, in the fine and practical arts, and in other forms of æsthetic expression.

"Continue the process of reorganizing the school's procedure so as to give the child continuous experience in the processes of democratic living.

"Discard the idea that the activity program is something that may be allotted to a period or session of the school day. Cultivate the idea that it is a change of emphasis in the theory and practice of teaching that modifies the school's total relation to the child and therefore modifies the organization of the child's entire school day.

"Give more attention to cultivating the mutual relationships of parents and teachers in guiding the child's educational growth and to developing the relationships of the school with the home and community."

One of the most difficult problems involved in this introduction of the Activity Program is the retraining and reorientation of thousands of teachers who had become skilled interpreters of the traditional curricula and methods of teaching with which they were familiar. It is significant that so much of this retraining is being undertaken in democratically organized teacher workshops (*q.v.*) which are in themselves the embodiment of the cooperative planning, creative expression, and self-evaluation that are the core of any successful Activity Program.

The reeducation of teachers that is necessitated by the influence of the Activity Program is complicated by the fact that the Activity Program is more than a method of teaching. The Activity Program is most meaningful when it is seen as a reflection of an educational philosophy that influences all phases of educational procedures, from the type of classroom discipline to the nature of the curriculum. The hasty adoption of the Activity Program by schools without adequate provision for in-service education of teachers has led many teachers to imitate the superficial characteristics of the Activity Program before they understood the purpose of the changes they introduced. Such teachers have tried to introduce activities borrowed from other teachers only to find that these activities had little meaning for their pupils. They have rearranged the furniture in their rooms, organized classes into committees, kept detailed "log books" (see *DIARY, CLASS*), and required that all pupils engage in research activities, only to find that they could not see the educational gains which other teachers reported. Many of the objections that have been raised to the waste of time and the purposelessness of the Activity Program are not really criticisms of the Activity Program when used with insight; they are criticisms of procedures which bear a superficial resemblance to the Activity Program but which are essentially far removed from the philosophy and the practices of a well-planned and expertly administered Activity Program.

It is significant that much of the preceding discussion related to the elementary school, for the Activity Program has had much more influence on elementary education than on secondary education. Such programs of reorganization as the *broad-fields approach*, and the many variants of the *core curriculum*,

and the concept of the *community school* (*q.v.*) endeavor to do for the secondary school what the Activity Program is doing for the elementary school. They, too, represent a reaction against traditional subject-matter dominated organizations and an affirmation of the principles of experiential learning and the creative development of well-adjusted individuality within a framework of cooperative effort and communal well-being. Such experiments as the Eight Year Study (*q.v.*) have done much to show the value of newer instructional practices in secondary schools and have stimulated the revision of curricula and methods in these schools.

One of the major difficulties attending the Activity Program in elementary schools is that the graduates of these schools enter secondary schools which are organized on a highly departmentalized basis. This difficulty reflects not a basic lack of harmony between progressive elementary education and progressive secondary education but an unfortunate lack of articulation between an elementary school program that is organized in terms of children's needs and interests and a secondary school curriculum planned in terms of fixed subject matter boundaries. Problems of articulation between elementary and secondary schools should be few when both are activated by a common philosophy and common basic principles. (See CURRICULUM, ELEMENTARY EDUCATION, PROGRESSIVE EDUCATION, SECONDARY EDUCATION.) J.J.L.

ADAPTABILITY. *Adaptability* may be defined as the ability of an individual to adjust his behavior to the general environ-

ment or a particular social situation. In contrast, *adaptation* may mean the ability to maintain ones self in a certain environment and may thus include the modification or adjustment of the environment to the needs of the organism. It is important in education to be clear concerning the degree to which a young person is learning to be an active factor in his physical and social environment so that he constructively promotes the development of himself and others, rather than merely learns to accept conditions as they are. W.F.B.

ADAPTATIONS—See MORRISON PLAN.

ADJUSTMENT—See MENTAL HYGIENE.

ADMINISTRATION, SCHOOL. **Functions of School Administration.** Public education in the United States has attained the proportions of a big business enterprise. The schools now enroll nearly thirty million children, taught by nearly one million teachers in more than a quarter-million schools. It is the function of school administration to plan for and to set up the channels through which this educational enterprise may be carried on. The administration must provide for school buildings and equipment, the employment and supervision of teachers, the purchase of instructional materials and supplies, the transportation of pupils, and many other phases of business management.

Teaching pupils is the primary function of the school to which administration is an aid. Administration is never an end in itself, but only a means to an end. To keep schools in operation there are hundreds of details which must be planned and executed in order that the instructional process may be carried on by the teachers. All such planning and executing of the plans either by administrative officers or by teachers, is the function of school administration.

Theories of Administration. Two principal theories of school administration may be characterized as the executive and the democratic. Under the executive theory of school administration it is considered best to have one or more persons directly responsible for the formulation and the execution of the policies of the school. This theory developed parallel with the theory of business administration in which efficiency in production and management were the chief objec-

tives. Under conditions of rapid expansion in public education during the latter part of the nineteenth and early part of the twentieth centuries, this theory was accepted and adopted by the schools.

The second theory, that of democratic administration, has grown out of the recognition that policy making and policy executing cannot be separated, and that all those who have a share in the work of the school should participate in planning. Democratic administration recognizes both the assistance to the administration that teachers can give and the opportunities it affords for in-service growth of teachers. It recognizes the principle of delegated authority and the principle of shared responsibility.

Evaluation of Administration. Any theory of administration or form of administrative organization must be evaluated, in the final analysis, in terms of its effect upon the educational processes. When education is conceived as growth of individual children and young people toward socially and personally desirable goals, administration must foster such development. That administration which improves the learning condition, provides for effective adaptation of the program to meet the needs of individual children, and stimulates pupil interest and fosters the development of attitudes and ideals is fulfilling its function. School administration, thus, becomes a means for reaching the objectives set up by the schools and by society, and must be evaluated in terms of its contributions to that objective.

Administrative Machinery. The administrative machinery of the state school system may be divided into two groups according to the agencies to which the authority to carry on educational functions have been delegated. These are the agencies of state-wide jurisdiction, the state board of education and state department of education and those of local jurisdiction, local boards of education and administrative staffs. The size and organization of state departments differs greatly in the various states. The number of persons employed ranges from fewer than ten to more than six hundred. In most states there is a third agency that is intermediary between the state and the district, such as the county, township or town. Broadly considered, however, these intermediate agencies may be classed as local.

The state administrative machinery is a state board of education and a chief state school officer who is in charge of the state department of education. State departments carry on functions affecting all the schools, such as supervision of attendance and census, distribution of state aid, enforcement of the state schools laws, certification of teachers, curriculum construction research, and general supervision of all the schools.

Under the local machinery for school administration is the board of education and one or more officers directly responsible to the board and the administrative offices. Here again, the size and the complexity of the administrative office vary in accordance with the size and complexity of the school system. The local unit carries on such functions as business administration, public relations, attendance supervision, employment and supervision of personnel.

Administrative Organization. The administrative organization of a local school system known as the *line and staff* has become the predominating one. This consists of a direct line of authority from the board of education to the superintendent to the principals to teachers and to pupils. In reverse order, the line of responsibility extends from pupils to teachers to principals to superintendent and to the board of education. Staff officers in this organization are persons who perform functions not directly in the line of authority such as the business management, supervision, management of transportation, etc. Persons who perform such functions are under the direct authority of the superintendent and may be considered as extensions of his office with advisory relationship to principals and teachers.

The *unit type* of organization is that form in which there is one executive officer, the superintendent of schools. This officer is directly responsible to the board of education and under his direct control and supervision are all the other personnel of the school. School administrators generally regard the unit type as the most desirable form of administrative organization.

When there are two persons at the head of the system, usually a superintendent and business manager, both directly responsible to the board of education, the organization is spoken of as the *dual type*. The theory supporting this form of organization is that

both the educational and the business management functions are of sufficient importance to warrant executive heads who are directly responsible to the board of education. The weakness of the system is that differences of opinion concerning theories or functions of the two officers may lead to conflicts which are detrimental to the efficiency of the school and the achievement of its objectives.

When there are more than two persons at the head of functions or divisions of the school system, each responsible directly to the board of education, the system is characterized as the *multiple type* of administrative organization. The weakness of this organization is similar to that of the dual type, except that the defects may be increased.

Teacher Participation in School Administration. Teacher participation in the administration of the school is not an innovation in education. Teachers always have been and will continue to be important participants in the administration of the schools. Schools could scarcely operate without the teachers' contributions to their administration. All phases of management in the classroom, in the halls, on the playground, and in the community, are directly related to and often involve administrative problems that are cared for in large part by the teachers. If one reviews the activities engaged in by a typical teacher in a city school system, he sees that the teacher often directs extra-curricular activities, manages libraries, keeps various records, selects and accounts for textbooks and other school equipment, deals with pupils, confers with parents, participates in public relations programs, and often serves on committees which may formulate salary schedules, prepare and review budgets, revise courses of study, plan curriculums, and determine other policies of the school.

Those who emphasize teacher participation in school administration recognize the important relation that teachers already play in the management of the school and would seek to set up channels through which such participants may receive recognition in school administration.

One of the most frequently recognized forms of organization is the teachers council (*q.v.*) to which representatives are elected either by divisions of the school system or teaching interests. Such participation of teachers enables the administration to make

fuller use of the resources of the staff and provides a new incentive for in-service growth of teachers.

Pupil Participation in School Administration. In some school systems, democracy in administration is extended to include the pupils. In such an organization pupils participate with teachers and administrators to formulate and execute school policies. While it should be recognized that pupils may not participate to the same extent nor always in the same areas as the teachers or administrators, the plan seeks to utilize and develop the contributions of pupil leaders in the administration of the school. Fundamentally, it serves to foster in the student body a sense of belonging and of participation in the work of the school.

Pupil participation is frequently secured through the organization of a student council to which pupils are elected either from classes or homerooms. The elected representatives of the student body speak not only for themselves, but for the entire school. Their contributions are often helpful in program planning and may benefit the pupil representatives.

Centralized Administration. The administration of the schools of a state or country may be organized on a centralized or on a decentralized plan. In the United States, education is considered as a state function and within each state there is both a centralized and a decentralized plan of organization. Centralized administration refers to the state administrative organization that is responsible for certain functions that are performed on a state-wide basis, such as the certification of teachers, the making of certain uniform reports, and the keeping of uniform records of attendance and finance. Decentralized administration refers to the separate administrative organization in the various local units which carry on the functions of employment of personnel, provision of teaching materials, erection and maintenance of buildings, etc. The tendency to place certain educational functions under the state organization rather than under the local organization is definitely one of centralization. In all states, with the possible exception of Delaware, the administration is more highly decentralized than centralized. Quite the opposite is true in certain foreign countries in which a centralized administration carries on all or nearly all the functions of state and local

school administration. The proponents of centralization point to the greater efficiency and unity that is possible under this plan, whereas those who favor the decentralized plan hold that it keeps the schools close to the people, makes them responsive to local needs, and stimulates local interest in education.

Selection and Education of Administrators. The chief administrator of a school is selected and appointed by the board of education. In making the selection, the board should take into consideration those qualities which an administrator should possess. The board should consult with various agencies, such as college and university placement officers, state departments of education, and other successful administrators. Perhaps the most important single function of a board of education is to select the right person to administer the schools.

The administrators should possess outstanding qualities of leadership. The American Association of School Administrators has outlined the following qualifications.

1. Ability to stimulate and encourage growth among members of the teaching staff.

2. Ability to organize members of the teaching staff so there is freedom for and encouragement of creative contributions to instructional improvement.

3. Ability to keep employees working as individuals and at the same time as a group with common objectives and a common goal.

4. Ability to direct the implementation of those services and policies which are recognized as sound and practicable.

In addition, he should have a pleasing personality, be able to meet people well, and take a genuine interest in the life and work of his community. The school administrator should have a broad cultural education and sound professional training. The minimum qualifications usually specified are the A.B. degree. In most schools, however, especially in the larger ones, the superintendent should have three years of graduate work terminating in the degree Ph.D. or Ed.D. From the standpoint of both his work and his compensation, the superintendent should maintain as high professional standards as the physician, the lawyer, or other professional worker.

Elementary and Secondary School Supervision. Elementary and secondary school supervision is usually distinguished

from administration to encompass those function of education which are directly related to the improvement of classroom instruction. Supervision is a very important area of the superintendent's work and although he may be assisted by a staff of special supervisors who do most of the supervision, he should be thoroughly trained in methods and techniques of teaching.

In the elementary school, supervision is usually carried on by special supervisors in charge of a division, such as primary, intermediate, or upper elementary grades. Another plan is to have special supervisors work in their respective fields of specialization, such as music, art, etc. On the secondary level, supervision is usually the responsibility of the principals and department heads. The organization and development of supervisory programs in both elementary and secondary schools is usually the direct responsibility of the superintendent or one of his assistants.

Many educators object to the way in which principals and superintendents emphasize their administrative rather than their supervisory functions. These critics question the wisdom of having the principal concern himself more with the smooth operation of the school organization than with the improvement of the pupil's educational experiences. This objection does not belittle the importance or the complexity of the administrative problems associated with running even a small school, but it does suggest that many principals and superintendents do not take full advantage of the opportunities for professional leadership of their teachers which are afforded by their positions. There is, however, no basic conflict between administration and supervision and the principal need not be an inefficient administrator in order to be a stimulating supervisor. (See BOARD OF EDUCATION; PRINCIPAL; SUPERINTENDENT; SUPERVISION OF INSTRUCTION.)

ADOLESCENCE

Standards for Superintendents of Schools, American Association of School Administrators (National Education Association, Washington, D. C., 1939).

The Superintendent of Schools and His Work, American Association of School Administrators (National Education Association, Washington, D. C., 1940).

ADOLESCENCE. Adolescence is that indeterminate period of a person's life from the time when he first begins to show signs of maturity to the time when adulthood is achieved. Though all of childhood is a period of growth and all of life an adjustment to change and changing demands, changes occurring during the period of adolescence have a heightened quality. This quality derives from the fact that by the end of the adolescent period those characteristics must be obtained which at last change one from the dependent child getting his support and security from the adults who have authority over him to the mature man or woman who must properly fulfill the functions both of his sex and of his adulthood. Full adulthood implies not only readiness on the part of a person to take responsibility for himself but also, in his (or her) turn, to give support and security to the young. Adolescence need not be the period of "storm and stress" by which some writers characterize it. Storm and stress will occur if the adolescent is plunged headlong into adulthood, or kept from attaining the long-awaited goal of adulthood, or if the mores of adulthood which he is asked to adopt are conflicting.

Education for the change of status from immaturity to maturity should begin in early childhood. The strings which hold the child to the authority and discipline should be loosened gradually and broken one by one as the ability for self-responsibility in the specific area has been attained. Education for self-responsibility and the giving of responsibility must go hand in hand if either is to be successful. Both must be long-term processes just as physical growth is a long-term process. Again, just as the rate of physical growth is different for different parts of the body—some organs having attained their maturity when others are just beginning to develop—so do mental and emotional skills and attitudes also grow at different rates. This means that the adolescent is adolescent in only some respects, while he is a child in others, and an adult in the rest.

This naturally uneven pattern of growth

causes many of the problems of the adolescent. In the first place, the adolescent himself veers from the desire to be treated as an adult to the desire to be protected like a child. Likewise, his parents and teachers see-saw in their treatment of him, expecting mature self-responsibility at one time and restricting him like a child at other times. Unfortunately, the occasion when the adolescent desires freedom and responsibility is not necessarily the occasion when the adult thinks he is ready for it, and on the other hand, he is often given responsibility on those very occasions when he feels least sure of himself and least eager to take it.

If the growth pattern were uneven but similar for all children, then parents and teachers could learn what it is and guide their own behavior towards youth accordingly. However, the growth pattern is, to a large extent, different for different children. Full height is reached by different children at different ages. Sex maturity has a very wide age range though it is generally true that both *puberty* (the first stage of adolescence) and maturity are reached earlier by girls than by boys, the age range of the onset of puberty being about 10 to 14 years for girls, and 12 to 16 for boys. For any one child, the growth curve of intellectual ability has no predictable relationship to his growth in height, nor to his sexual maturity. Adults must therefore watch the individual child and adjust their demands and restrictions accordingly, if they wish to help emotional growth to proceed and to avoid causing maladjustments.

Individual differences in the pattern of growth may also bring about acute maladjustment between the adolescent child and his friends. A physically mature girl of thirteen no longer has the interests of her former friend who is also thirteen but who is still in the earliest stages of puberty, and yet the fifteen-year-old girls whom she resembles physically find her too immature mentally, too childish in other ways. Adolescence is a time when many new groupings of friends are formed. During junior and senior high school years, students are constantly striving for status in both a group of their own sex and in a heterosexual group.

The ease with which satisfactory heterosexual status is attained is a function not only of sex-maturity and sex-attractiveness but of every personal quality. Unpopularity with

ADOLESCENCE

the opposite sex can be caused by a temperament which was set by the training the child received in the first six or ten years of his life. Unsatisfactory heterosexual adjustment may also arise through the adolescent's insecure feelings towards his own maturing body. Since adolescence is a time of rapid growth in many phases visible to the child—height, weight, genitalia, secondary sex characteristics—it is natural that he should be interested in and concerned about the rate of growth in these areas and that he should be continually comparing himself with others. A certain amount of anxiety because of slowness of growth or pride because of rapid growth compared with that of friends is natural. Unhealthy attitudes toward the body are sometimes developed at this period. Oftentimes, however, they have their start at a much earlier age. Attitude toward one's own body always enters into the concept of one's self which begins to develop in infancy. The attitude of adults towards their own bodies and towards the baby's body, their evaluation as to what is "nice and what is not nice" to do or to say will affect the young, child's feelings towards the body and later will have an effect on his attitudes towards sex and sex behavior. The groundwork for a good or poor heterosexual adjustment is thus laid long before adolescence is reached.

Strain during adolescence may also be brought about by the youth's expectancy that very soon sharp demands will be made upon him which he feels he is not going to be able to meet. The knowledge that it will soon be necessary for him to become self-supporting makes the adolescent lose patience with a school curriculum which does not seem in any way to be training him to make a living. During a depression, knowledge that jobs are not to be had may keep the adolescent in school longer than the permissive school leaving age, even though there may be little enthusiasm for study.

Maladjustment during adolescence may also be brought about through the fact that social maturity, the gaining of adult status in society, is delayed long past organic maturation. In our society, taboos with regard to pre-marital relationships are strong enough to arouse guilt feelings when they have been transgressed, yet weak enough to make every adolescent feel concerned with determining how much petting is "all right" and where

the line must be drawn. The delay in becoming "your own boss" is equally frustrating to many an adolescent who is regarded as socially immature because of the arrangements of society and not primarily because of limitations in himself. Though adults can retard emotional maturity and social adulthood for a very long time; they cannot delay physical adulthood.

The extension of secondary school education to include more and more children therefore accentuates problems which were not so acute formerly. When the high school enrolled only the children of a fairly homogeneous socio-economic group many of whom looked forward to going to college and to entering a profession, there was often enough personal drive and family pressure to make going to high school "the thing to do." Today, however, the high schools enroll adolescents who have no such strong personal drive. To such students, attending high school seems to be more an unwanted prolongation of their elementary school childhood than a preparation for and an introduction to their participation in an adult world. They find, moreover, that the high school curriculum does not concern itself with the questions that trouble them. The girl who wonders how she can convince her parents that she is no longer a little child, the boy who is impatient to earn his own money rather than have to depend on an inadequate allowance, the student who is convinced that he has the solution for the world's social and economic problems—all these find little that is interesting or challenging in the love life of Sir Lancelot or the many ways in which one can prove that two triangles are congruent. The high school curriculum is beginning to reflect the needs of adolescents and the changes that have already been introduced support the hope that the secondary school may some day be an appropriate place for all adolescents. (See CURRICULUM; SECONDARY EDUCATION.)

The adjustment of secondary school procedures to adolescent needs is complicated by the fact that sex differences in the rate of maturation are greatest during these years. The teacher of a second year class in high school may have a group of fifteen-year-old boys and girls, but he really has a group of fifteen-year-old boys and fifteen-year-old young women. The novel

which the girls find so interesting may therefore be so much more adult in its appeal that the boys think it silly. Moreover, the bright girl whose mental and social interests are ahead of her years, experiences difficulty in finding any boys in her class, or even in her school, who share her interests.

Though educators are eager to extend the period of compulsory education through the adolescent years, they are becoming increasingly aware of the many problems that must be solved if the extension of secondary education is to be successful. B.B.F.

ADULT EDUCATION. The term adult education means all things to all men. To the housewife in Pittsburgh it may mean that her mother who was born in Poland can learn English in a free night school. To a chemistry professor in a midwestern university it may recall his twenty students in correspondence courses. To a superintendent in a southern state, it may be identified with an evening school staffed by teachers of home economics, agriculture, and shop; while to another administrator it may signify his efforts with the parent-teacher association to get cinders for the play field. To professional adult educators, adult education may be returning to a creative endeavor, directing social change, attaining security, or seeing the view.

In these varied definitions of adult education, we have five common elements. (1) The definition varies with the personal experience of the individual making the definition, and contains few of those common denominators found in descriptions of other fields like elementary education. (2) Adult education is a process operating on someone else, rarely on the person who is defining it. (3) Adult edu-

cation is ordinarily assumed to be undertaken only when the individual himself is conscious of a basic need. (4) Despite the admonitions of adult educators to one another to achieve a magically different methodology, only those activities are recognized as adult education which are packaged in orthodox forms such as lectures, discussions, forums; reading (on both sides of the question); radio or dramatic presentations which are "good"; motion pictures which are scientifically or historically acceptable in their content. (5) Adult education is more often defined in terms of values than it is in terms of psychological processes. There is no "bad" adult education. To the person defining it, the term always implies some "good" activity.

These boundaries exclude from the field of adult education such behavior-changing as formation of public policy through debates in pressure groups and legislative halls, development of consumer habits through advertising, and formation of attitudes through motion pictures and planned campaigns in the press. The adult educator who wishes to study his field functionally in terms of all the forces which affect the behavior of men and women is in a dilemma: he must either relegate to other fields like propaganda some of the most important of these manifestations or he must take for his province practically the whole of the conscious world. Despite the magnitude of the latter task, it yields greater returns in a study of how men and women are to control their own destinies through education.

Adult education thus defined might be a process of behavior-changing. The latter term, however, needs interpretation; for it includes changes in the individual which preface changes in behavior, as well as overt actions themselves. And it may result from purposes of the individual being educated or from purposes of others. Thus the emotional adaptations in the person who listens to the symphony every Friday or the one who sways to a jitterbug band every night are evidences of an education in tastes. Likewise, continuous, self-initiated discussion in a club or continuous exhortations by a rabble-rouser, either of which may result in an individual's writing his Congressman, both signify that the educational process is going on. The end results for the individual or for society may be either

good or bad: neither should be excluded from the all-inclusive term, *adult education*. This does not relieve the educator or the layman of the necessity for defining "good" education—in fact it becomes his responsibility when he fully understands the extent of his field.

Scope of Adult Education. *Job Efficiency and Economic Security.* In this wealthiest of all countries where riches are to be had in return for skill and daring in exploiting them, the most powerful dynamics in adult education have been two interchanging motives: job efficiency and economic security. Both employer and employed groups as well as independent agents have been instrumental in promoting vocational (including professional and agricultural) training under public and private auspices.

A series of devastating depressions has made clear to citizens of the United States, however, that illimitable resources and skill in their exploitation are not enough to assure security to all economic groups. Industrial workers have answered the challenge to unemployment by education for organization through unions and a special set-up of workers schools. Independent farmers, farm laborers, and professional people have in turn established their own organizations for a solution of economic ills. Confronted with what they have considered inroads on their rights, employing groups have resorted to many schemes for educating both the public and their own employees to the "business point of view."

Personal Growth

The overwhelming weight of the job efficiency purpose is somewhat misleading, for often the individual's search for job adjustment is part of a larger search for personal happiness. In response to this basic need, men and women have set up agencies to correct educational deficiencies (particularly in reading and writing), to provide recreation through the arts and games, to give spiritual or religious satisfaction. In response to other motives, commercial agencies have capitalized on the recreational aspect of this basic need and have so much set the public fashion in leisure time activities that non-profit making agencies often must give lip-service to these new tastes or be forced to close their doors.

Home and Family Life

As in most human societies, the family

in the United States is a basic social pattern and has been the motive power for much adult education by the home itself, and by other agencies operating in cooperation with the home. The terms "marriage clinic," "parent education," (*q.v.*) "home economics education," (*q.v.*) and "family life education" (*q.v.*) suggest the scope and variety of interpretation in this field.

Education to Develop Social and Political Controls

There has been a growing realization in the United States that the welfare of the individual is dependent on the welfare of the group; and that social controls are a concomitant of personal well-being. How profound a change this belief induces in American culture can be appreciated only if one understands the individualistic nature of our pioneering past. The resulting education in social and political controls has involved such fields as adjustment of foreign born to the American culture (Americanization); creation of tastes in and control of consumer goods; provision of consumer services (medical care, schools, recreation, social security measures); control and improvement of government service to meet the expanding concept of governmental functions; development of a defense against force both within and without the country (police and military education); and development of international controls. Education in these areas has been cross-fertilized by all the other areas, particularly that of job efficiency. (See AMERICANIZATION; CONSUMER EDUCATION; MILITARY EDUCATION.)

Agencies and Media. By their own admission, adult education agencies divide themselves into action and non-action groups. Some of the former show proper pride in their role as "education for action" groups; while others modestly dub themselves propaganda agencies and are persuaded of their educational nature only through being shown the scope of adult education. Most of the business, labor, agricultural, and civic organizations are in this first classification. Opposed to these aggressive elements are the non-action or reflective agencies including most school groups (workers schools are generally an exception to this rule); and other institutions like the library. Most of these agencies will vigorously maintain that action is the prerogative of the individual learner and not

the business of the institution. This cleavage between types of agencies ordinarily appears only when a controversial public question is under discussion.

Other classifications frequently employed are *formal* and *informal* (a division based on methodology); *profit-making* and *non-profit-making*; *public* and *private*. Some writers divide the field as well as the agencies into *remedial* education designed to correct deficiencies in youth education, and *adult education proper* which concerns adult needs and abilities only. Still others draw a poorly conceived distinction between *workers' education* (*q.v.*) and *adult education*, refusing to see the former as a part of the latter.

Whatever the classification, agencies operating in the field include public and private schools and Federal agencies; universities and colleges, including extension divisions and post-collegiate set-ups; clubs, societies, and associations; museums and libraries; religious, social welfare, and other types of institutions; councils and other coordinating bodies; forums, political parties, and other miscellaneous groups.

The media used appeal to all the senses, and include the spoken word in radio and from the lecture platform, as well as printed matter and the motion picture.

The Central Problem of Adult Education. Quite unconscious of any unity of purpose, job efficiency education has bridged the gap between the buying-and-selling age of the 18th century and the power-age of the present era. Despite a certain clinging to old ways among farmers, tradesmen, and small business men, most workers have made the adjustment to the industrial times; while corporations have burst their shackles entirely and are now operating on a world scale. Despite the fact that media of communication are world-wide, much of education for economic, political, and social controls still suffers from outmoded themes. Some of it has been devoted to patching the most obvious rips in the social fabric; and no effective means has been found of meeting the challenge of an international economy with education for international understanding and control.

The disease which has been the root of the difficulty among the non-profit-making agencies particularly has been a specious belief that diversity of control and variation in pur-

pose are the essence of free educational institutions. The central problem of adult education in the United States therefore becomes that of keeping pace with the aspirations of men and women. To do this, adult education agencies must clarify and unify their purposes so that they may cooperate with agencies in other lands in creating social and political controls which will parallel those economic ones already established. AERONAUTICAL EDUCATION. The term "aeronautics" has reference to the art and science of flying and navigating aircraft. The latter may be divided into two categories: (1) the heavier than air machines such as airplanes and autogyros; and (2) structures or devices lighter than air such as kites, gliders, balloons, and parachutes. The aeronautical industries may also be grouped on the basis of those that manufacture aircraft, engines, and accessories such as propellers, tires and instruments; and those that use the aircraft.

Aeronautical education is conducted extensively in the United States in vocational schools under public as well as private auspices, in public and private technical institutes, and in colleges and universities. The public schools of secondary grade have placed the major emphasis upon training for ground-work; such as training for (1) airplane mechanics and (2) aircraft engine mechanics. Recognizing the great value in progress in air transportation and in training aviation mechanics, the Vocational Division of the United State Office of Education (*q.v.*) (then the Trade and Industrial Division of the Federal

Board for Vocational Education) early directed its attention to this area of vocational training. Bulletin No. 142, *Vocational Training for Aviation Mechanics*, revised in 1932 by Robert W. Hambrook of the U. S. Office of Education, is a carefully prepared bulletin of 285 pages giving much useful information on the subject. It was a pioneer production.

Many persons 16 years of age and over are receiving apprenticeship training under both public and private auspices for many kinds of skilled occupations or trades—such as aircraft sheet metal work and aircraft welding—connected with aircraft production. As an example of private initiative, attention is called to the Ford Aircraft School at the River Rouge plant where 3,000 apprentices are getting valuable training for jobs on Pratt and Whitney airplane engines. In another part of the same plant 1,800 sailors are getting intensive mechanical training. Both of these training programs are in addition to the extensive enrollment in the long established Ford Apprentice School which formerly prepared boys for automotive trades. Among the public schools giving valuable training for aircraft production, maintenance and repair, the Burgard Vocational High School of Buffalo, New York, deserves special mention.

Aeronautical training at the technical institute and college level is given through a variety of courses such as: (1) aerodynamics, the study of disturbances of the air caused by the passages of aircraft; and (2) aerial navigation, the art and science of determining the position of aircraft (as for example, out at sea), and of setting its course in the direction desired. Other courses include aircraft structures; aircraft design; airplane engine design; radio operation; and instrument design, maintenance, and repair.

Considerable attention is given in especially equipped centers to research in aeronautics.

(See AVIATION AND THE CURRICULUM; VOCATIONAL EDUCATION.)

AGE EQUIVALENTS—See **NORMS**.

AGE-GRADE PROGRESS—See **PROMOTION**.

AGE NORMS—See **NORMS**.

AGE SCALE. A scale divided into a series of subtests placed at definite year levels is called an age scale. Tests are ordinarily placed at a given age level if the average child of that chronological age can pass the test. There are usually a uniform number of subtests, each contributing the same number of "months" to the final score, at each age level. The highest age level at which an individual passes all tests is known as his *basal age*. The Stanford Revision of the Binet-Simon tests is an age scale.

A *point scale* is one in which presentation of problems and method of scoring are such that credit for passing a test or part of a test is given in terms of score units or point scores, rather than in terms of months. This arrangement generally allows for the assignment of partial credit to a response, as distinguished from the "all-or-none" method of scoring characteristic of age scales. Also the norms of a point scale may be revised more easily than those of an age scale, nor is it necessary to develop a complete age standardization for every test appearing on a point scale. In general, the point scale is more flexible in organization than the age scale.

AGRICULTURAL EDUCATION. Agricultural education as we know it today is comparatively new, much of its basic data having been obtained during the past century. The idea that agricultural practices might be improved is old and its conception difficult to establish. Josephus, in his writings, mentioned tillage practices as affecting yields; and Cato, Varro, and others wrote on improved husbandry.

The need for agricultural improvement in our country was beginning to be discussed in colonial days. Following the Revolutionary War emphasis was laid on the necessity for improved agricultural practices. Washington in his writings shows a clear understanding of the cropping and soil management problems of his day. Even then there was evidence of soil depletion, a need for improved

varieties of field crops, vegetables, and fruits, and for better strains of livestock. Out of these needs began the improvement of agriculture and the founding of agricultural education. Many wealthy landowners imported improved strains of cattle from England, sheep from Spain, and many varieties of crops from the old world.

American agriculture, developing in the pattern already established in Europe, reveals throughout its history an interest in better farming. Journals and societies devoted to agricultural improvement are numerous. Of the former, the *American Farmer*, Baltimore; the *Plow Boy*, Albany (1819); the *New England Farmer*, Boston (1822); and the *Southern Agriculturist*, Charleston (1828), are the earliest. The first agricultural societies were established in New York (1791), in Massachusetts (1792), in Charleston, South Carolina (1874), and in Philadelphia (1875). These societies held plowing matches, gave premiums for outstanding farm products, and in one instance operated a small experimental farm.

Between 1800 and 1850, attempts were made in various states to establish agricultural colleges or to teach plant and animal production in colleges already in operation. In 1825 *The New England Farmer* advocated a plan for establishing the Massachusetts Agricultural College. The New York state legislature authorized the Peoples College in 1853, with agriculture an important part of the curriculum. Ohio, Connecticut, Maryland, Wisconsin, and Illinois all report attempts before 1850 to establish agricultural colleges.

Michigan in 1855 authorized the establishment of the Agricultural College of the State of Michigan. The site selected was "a large farm near Lansing" and the purpose of the college was to improve and teach the science and practice of agriculture. This is considered the first of the agricultural colleges. In the same year the Pennsylvania legislature appropriated \$10,000 as aid for the agricultural school that later became Pennsylvania State College.

Out of this agitation and the efforts of the states grew a demand for federal aid to stimulate the establishment of an agricultural college in every state in the Union. The first land grant bill, introduced in the House of Representatives by Justin S. Morrill of Ver-

mont, December 14, 1857, passed in both houses, but was vetoed by President Buchanan. Another bill, almost identical with the first, was introduced on December 16, 1861, by Mr. Morrill, passed by both houses of Congress, and signed by President Lincoln, July 2, 1862.

The land grant act provided that, upon acceptance of its provisions, each state should receive 30,000 acres of public land for each of its members of Congress, income from the land to be used to establish and maintain a college of agriculture and mechanic arts. Thus definitely began the far-reaching program of agricultural education for the entire United States. Institutions created under this act are known as Land Grant Colleges or Universities (*q.v.*).

Today every state in the Union has its college of agriculture, supported partly by federal and partly by state funds. Some states used all their federal funds to support separate institutions, commonly known as agricultural or land grant colleges. Other states decreed that their land grant colleges should be attached to a state university or to an endowed university. In thirteen states the income from the land grant was apportioned among three or more educational institutions.

The first years of existence were not easy for the newborn agricultural colleges. Educators in liberal arts colleges were frankly antagonistic, farmers were skeptical, and the professors were hampered by a lack of practical training and a scarcity of scientific teaching material. All of these handicaps resulted in very small student enrollments over a considerable period of time.

The situation is quite different now. Colleges of agriculture have faculties of well-trained scientists, each a specialist in his field. Courses have multiplied and today students may choose their own fields of agricultural education. Each college is well served by strong departments of physical, biological, and social sciences.

Student enrollments have increased rapidly during the past thirty years, and state legislatures generally have made liberal appropriations for buildings, equipment, and maintenance. Early opposition has been largely replaced by enthusiastic acceptance of the discoveries made and the new farming practices taught by the staff members.

AGRICULTURAL EDUCATION

Colleges of agriculture offer a variety of curricula ranging from short practical courses, a few weeks in length, to four-year groups of studies leading to a bachelor of science and the doctor of philosophy degrees.

In addition to the teaching faculty each state maintains a well-equipped experiment station adequately staffed by research workers. This is usually connected with the agricultural college. The stations carry on a wide range of studies on various farm problems. Through plant breeding have been produced many improved varieties of grains, fruit, and vegetables, and new plants have been imported and adapted to local conditions. Disease prevention and insect control have been accomplished in many instances. Farm animals have been studied with the purpose of improvement and adaptation. Feeding, housing, and care of animals have been subjects of many long-time, carefully planned experiments.

In short, the agricultural experiment station provides much of the new information used by college teachers, the extension workers, and the general public.

The agricultural extension service is the newest phase of agricultural education and in most states is a part of the college of agriculture. Since only a small percentage of the farmers enroll in college, Congress decided that agricultural college information should be taken to the farmer. Before Agricultural Extension was organized this was done through farmers' institutes, but now the county extension agent is the local representative and is responsible for agricultural contacts with the farmers.

Through the local farmers' organizations, led by the county extension agent, plans for the county are formulated and educational meetings held. Specialists from the Agricultural Extension Service are available for county meetings upon call from the county agent. In addition to Experiment Station bulletins on many phases of agriculture, Extension publishes others that are distributed to farm families.

Another great agency promoting agricultural education is the United States Department of Agriculture (hereinafter called the U.S.D.A.). Organized as a department in 1862, its functions were rapidly expanded. In 1889 its chief became a member of the Presi-

dent's cabinet. Today the U.S.D.A., a vast organization with large appropriations for investigation and powers for regulation of state and interstate activities, is the head of the agricultural experiment stations and the agricultural extension organizations in the states. Through its leadership, research and extension programs are coordinated and unnecessary duplication avoided.

The U.S.D.A. maintains some regional agricultural experiment stations under its direct control. It also under some conditions locates research workers at state experiment stations for work on special projects. It publishes thousands of bulletins and reports available to farmers and other interested people. In addition to its educational and research features, the U.S.D.A., by authorization from Congress, has wide regulatory powers. It supervises meat and food inspection, importation of grains, meats, and fruits, and, through quarantine, the control of disease and parasites. Its bureaus furnish information concerning soils, weather, condition of crops, and market trends.

The latest big development in agricultural education is the teaching of vocational agriculture below college grade. This program was initiated formally by Congress in 1917 with the passage of the Smith-Hughes Act providing federal aid for the work and making definite plans for federal and state co-operation. Later federal acts have provided additional funds and regulations governing their uses. As is true with other federal co-operation, some of the federal funds must be matched by the state.

The teaching of vocational agriculture is in essence a high school program, beginning generally in the first high school year. The boys are organized into subject matter classes, such as animal husbandry, crops and soils, or farm management. Textbooks and bulletins are used for teaching and each member of the class has a home project that he looks after while studying a particular field. Thus the study becomes vocational in nature and practical in its application. Actual farming practice with livestock, crops, and farm management, is secured through these projects. Under the direction of the teacher, students make surveys of their home farms and draw up plans for the best use of the various fields.

The teachers of vocational agriculture are

graduates of agricultural colleges with special preparation for their chosen field of work. Their program also includes the organization of evening classes attended by older out-of-school farm boys and by adult farmers. The objectives of vocational agriculture are to teach farm boys to be efficient farmers, to give added instruction to adult farmers, and to train for rural leadership.

The teaching of vocational agriculture aided by federal funds has been in effect since 1918. Before that date only a few states had undertaken programs of vocational education below college grade. Today every state accepts the provisions of the Smith-Hughes and subsequent acts. State appropriations provide funds to match the federal money. Local high school districts pay a portion of the teachers' salaries and provide classrooms, shop, and needed equipment.

Many other organizations and agencies provide programs of agricultural education, directly and indirectly. The Grange, the Farmers' Union, and the Farm Bureau, for example, enroll thousands of members and induce actual participation in efforts to increase the farmers' income and raise standards of rural living. Farm journals published in every state find their way into a majority of rural homes.

From small beginnings in colonial times, when rural life was exceedingly difficult, agricultural education has grown into a series of popular and scientific programs, which have profound influence on agriculture and on rural life.

W.W.B.

AIMS OF EDUCATION. *General.* Education is a purposeful and ethical activity. Hence it is unthinkable without aims. Most generally speaking, those who devote themselves to education have already made an ethical decision; they want the younger generation to acquire skills and knowledge and to develop standards of conduct which will enable them to understand themselves and their society and to live a decent, happy, and productive life. Whatever one thinks (in terms of mere theory) about good and evil and their origin, no normal parent or educator wants to lead the young toward a state of mind where he prefers, for example, stealing to work, cheating to honesty, ignorance to wisdom, cruelty to sympathy, and slavery to freedom.

Of course, educators, like all other men, are exposed to differences in interpreting the contents of morality in a specific time and situation. A mediæval ascetic monk and a modern teacher diverge in their ideas about physical and mental hygiene. A pacifist and a nationalist educator differ greatly in their opinions about the permissible degree of interference of the State in civil life. In addition, there exists the pressure of dictatorial groups on the educator to convey, or conceal, facts according to the wishes of the powerful; and among teachers voluntary martyrs are as rare as among other people. Consequently there has been great variation in the exact definition of the aims of education.

One's opinion about this matter will naturally depend on his general philosophical, and especially on his ethical, views. If he believes that the ultimate values of humanity are not created by man, but are of transcendental character—either revealed by God or appearing in history as creations of an eternally self-revealing Logos—then he will also believe that the aims of education, in spite of a certain degree of adaptability to changing circumstances, are fundamentally immutable. This is the basic tenet of religious schools of education, as it was with all forms of Platonism. Modern "Idealism"—to use the current but rather vague term for all those modern philosophical schools of thought which hold to the ultimately persistent and transcendental character of values—is still "Platonic." The modern Idealist believes that through education and self-perfection man not only realizes his own self, but relates that self to universal values far greater and more persistent than his own transient individuality.

If, on the other hand, one believes that values are man-created, then they, and with them the aims of education, can never possess any absolute character. Let us call this school of thought the "sociological" or "pragmatic" school. Whereas the educational aims of the religious or idealistic schools of thought are necessarily of universal character (the ancient virtues of justice, fortitude, prudence, and temperance, and the Christian virtues of faith, hope, and charity, all combined as the Seven Cardinal Virtues), the aims of the sociological schools are often more closely tied up with specific purposes of the individual and of society (education as self-realiza-

tion, education toward happiness, education toward cooperation with specific forms of social organization as, for example, education for democracy). When this trend toward the specific is combined with increasing historical comparison, it often leads to the opinion that, since society seems to be in a state of continuous change, the formulation of definite aims in education violates what some believe the only social law that can be discerned—the law of change. Then the sociological schools of thought incline to neglect the problem of aims and values as being beyond scientific grasp. They become relativistic and eclectic, or their definitions, in order to avoid the dangers of fixation, become even more abstract and general than those of religious or idealistic schools of thought. The aim of education thereupon becomes more or less identical with its process, as is evidenced in the well known modern pragmatistical definition that education is growth and relative to nothing but more growth. Or the aim of education is described in such terms as “nobler ends,” “a complete life,” or “the satisfaction of well directed desires.”

Fortunately for the practical effect of education, these two ways of thinking about educational aims, the idealistic and the sociological, mingle in the reality of educational activity. In Plato the perfectly educated man was not only supposed to be nearest to the transcendental realm of ideas, but also to be the guardian of the state, with all its practical interests. In Christianity the ideal of the saint had to be complemented by that of the servant of the Church, which was not only the *communio sanctorum*, but an institution with a considerable number of temporal, and certainly not always holy, interests. In addition, priests were the teachers of the future political counselors in the offices of the princes, of the lay scholars, and of the nobility. All this brought classical Christian education often dangerously near to a utilitarian and pragmatistical attitude. Also the modern philosophical idealist knows that the realization of ideas does not take place through mere contemplation, but through helping ideas to become concrete. This requires action amidst all the shortcomings and compromises of reality.

On the other hand, the sociological schools have generally used highly ethical criteria for

the definition of the aims of education. As we know, they interpret the origin of aims and values differently from the idealists, but the effect on the educand is nevertheless largely in conformity with traditional moral ideas. By their adversaries, the sociologists—because of their derivation of aims and values from human interests—have often been called relativists, sceptics, or materialists. Yet, in relation to education, they have always placed the common or social interest above individual advantage. American pragmatism, especially, has emphasized democracy, not merely as a form of political association, but as a framework in which to develop a productive experimental attitude, cooperation, and a sense for freedom and independence. The aversion of the sociologists toward metaphysics, of course, makes it philosophically difficult for them to moor their aims and values in a deeper, more persistent ground, or to find definite criteria for selecting the good and lasting in the flow and flux of things. The religious and idealist schools, on the other hand, will always meet the objection that they lead their followers into a sphere in which empirical dogmatism and intolerance have grown. They could, however, reply that there is no productive human life without some kind of conscious or unconscious faith, and that the very thing they attempt is to lay the hidden and ultimately superrational essence of human life open.

In summarizing this general consideration of the aims of education one may say that education, as an activity which is tied to practical ethical purposes, renders extreme opinions about the aims of human conduct, as they may occur in mere theory, impossible. Faced with the responsibility of guiding the young, the different ways of educational thought converge much more than abstract philosophical schools. This becomes also evident in the more recent American publications about purposes and aims of education, as, for example, the *Cardinal Principles of Secondary Education* (1918), the *Issues of Secondary Education* (1936), and *The Purposes of Education in American Democracy* (1938).

However, the conflict between the metaphysical-idealist and the sociological-pragmatistical interpretation of the essence of human life and its aims has caused almost as much

hostility and confusion among educators as it has caused in other fields of thought and civilization. Future generations will have to overcome this conflict, not merely by dint of eclectic compromise, but by means of thorough philosophical analysis. Such analysis will have to deal particularly with the epistemological and psychological problems inherent in the relationship between the rational and the irrational spheres of life, with the relation between the exact sciences and the humanities, and finally with the relation between the so-called "conscious" and "unconscious" strata of the human mind. For this purpose the methods of philosophical inquiry which Kant has elaborated in his *Critique of Pure Reason* will be of fundamental importance, irrespective of the question as to whether one agrees with his results or not. In addition, the philosophy of education will have to utilize all modern research into the methodology of thought, from mathematics to biology, from medicine to historical and philosophical anthropology, and from experimental psychology to undogmatic forms of psychoanalysis.

Specific.

For the purpose of describing the specific aims of education one could choose a systematic arrangement; for example, one could describe the different trends in education according to their preference for transcendental or sociological, individualistic or political, contemplative or practical ideals. But such an arrangement would show, even more than our general considerations, that the texture of purpose in educational practice is too rich to be clearly dissected into its single threads. We choose, therefore, the historical way for a brief (and from the point of view of completeness certainly quite inadequate) treatment of the aims of education.

At the beginning of our western civilization, in Greece, we find two distinct forms of education, one in Periclean Athens, which had as its goal the *aner kalos kai agathos* (ἀνὴρ καλὸς καὶ ἀγαθός) the well built, harmonious and brave man, the other in Sparta, which had as its goal the disciplined and obedient warrior-citizen. The first is æsthetic, individualistic, and aristocratic (Athens was never a democracy in the modern sense); the second is collectivistic and totalitarian. Plato, who wrote his politico-educational utopia, the

Republic, after the defeat of Athens by Sparta which occurred in 404 B.C., tried to combine the Athenian æsthetic with the Spartan totalitarian ideal. He was probably subject also to influences from strongly socialized and centralized Egypt. The older Roman ideal of the *vir constans et fortis* (a loyal and brave man) resembled the Spartan aim of education more than the Athenian, but in the second century B.C. more and more Hellenistic influences were brought to bear on the susceptible minds of the Roman conquerors, until, during the centuries after Christ, international eclecticism took the place of a clearly discernible national ideal.

In the Christian Middle Ages the ascetic, transcendental ideal of the saint, the monk, or the hermit partly replaces the natural self-assertion of the ancient period. With spreading civilization, however, more worldly aims of education again emerge: the Christian knight who has to combine the fortitude of the trained warrior with the virtues of the Christian and with a refined moral and æsthetic taste. In the mediæval education for chivalry we have a precedent for the many later forms of caste education (the *courtier*, *le gentil-homme*, *der politische Mensch*, etc.). Too little attention has been given to the mediæval guild ideals. Since the fourteenth century there certainly existed not only secular city schools beside the old cathedral schools, but also proud conceptions about the education of a city craftsman or merchant. They demanded a mixture of elementary knowledge with mastership in the craft (system of apprenticeship). Even the mediæval universities, to which we owe the development of professional ideals, were included in the guild system; the professor of the scholastic university considered himself as much a member of a corporation with its specific laws, rights, seal, and code of honor, as any other mediæval guildsman.

The Renaissance developed the ideal of humanism which, in many branches, has moulded the aims of education up to the present. Its origin is generally connected with the "revival of ancient learning." But if the much used and misused term of humanism means anything, it must be referred historically to the growing liberation from external authority and to the growing individual self-confidence of the Renaissance type. This con-

fidence in one's own personality springs primarily from the widening horizons, the travels and explorations, the more empirical attitude, and the growing wealth and knowledge which first the upper classes of the Italian cities enjoyed and which then spread through most European countries.

Unfortunately the genuine spirit of the Renaissance became in the typical academic training of the following centuries one-sidedly identified with the learning of Greek and Latin. We say "unfortunately" not because we doubt in the least the value of ancient studies. We even consider them as an essential element in a civilization which does not want to be cut off from its own roots. But the identification of a "liberal" education with the knowledge of the ancient language has led to a whole series of difficulties in modern secondary and higher education: it separated the "liberal" from the scientific and applied studies, for it refused for too long a time to acknowledge the value of the latter for the appreciation of the deeper and finer values in individual and social life. This identification has also led to artificial, and often much too easy distinctions between the "educated" and the "uneducated"; it forced upon the people a one-sided selection of talents, mainly on the basis of linguistic abilities; and it kept many youths away from active interest in their actual environment. These disadvantages have brought about a reaction which not seldom tends to forget that there has never existed a dominating ideal in mankind which could do justice to all potential human desires at once, and which also tends to belittle the discipline of mind, the historical and international perspective, the development of style and taste, and the insistence on high standards characteristic of the humanist aim of education.

Naturally in different times and nations the humanist ideal has undergone considerable changes. It has included a wider range of subjects in order to accommodate itself to the progress of knowledge and to modern professional needs. The French aim of *culture générale*, and the German aim of *Allgemeinbildung* (universal education), as elaborated by Herbart (*q.v.*), are derivatives of the old humanist ideal. To a certain degree this is also true of the English-gentleman ideal (Locke). But the English-gentleman ideal, born out of

a mixture of the standards of chivalry and courtiership with Christian and humanist conceptions, has never been so closely tied up with primarily intellectual demands as continental academic humanism. Hence it has been able to incorporate gradually new social ideals until it has become a general criterion for decency, good manners, and a certain familiarity with cultural standards.

With the increase of popular demand for a share in political rights and the advantages of schooling, education for citizenship has become one of the foremost aims of the modern public schools. This is not essentially different in democratic and in dictatorial countries, for not even modern totalitarianism can dispense with the technical cooperation of its subjects, however one-sided, involuntary, and enforced it may be. Yet the totalitarian development displays a danger inherent in all identifications of educational aims with secular institutions, as every State necessarily is; namely, the absorption of the ethical and spiritual freedom of man by the demand of external loyalty to a limited and organizational aim. It will be one of the main tasks of modern democratic educational philosophy and practice to find ways of combining sound patriotism as well as political and economic cooperation of the citizen on the one hand with that degree of attachment to universal values which have made civilization possible.

ALL DAY NEIGHBORHOOD SCHOOLS. The All Day Neighborhood Schools are an attempt at applying the principles of the community school to the needs of a congested city.

Following six years of experimentation by the Chelsea School Project of the Public Education Association, the Board of Education of New York City on March 10, 1942, voted to establish All Day Neighborhood Schools. Thus was recognized the success of a pioneering project in the establishment of a community school in the heart of a crowded city. The practices of the school grew out of those developed by Caroline Pratt, founder of the City and Country School, who in turn had been greatly influenced by Dewey's (*q.v.*) philosophy. Its objectives, stated in a memorandum prepared for the New York City Board of Education, were (a) to introduce an all-day program of work and play for public school children that will contribute to the maximum development of each child so that his relationships with the home, school, and community may be more harmonious, (b) to demonstrate that school work can be integrated with out-of-school activities, as well as with expressional and manipulative activities, and (c) to develop a pattern of approach for the school as a community center, cooperating with the other Board of Education, city, and local community agencies.

A director and a staff from the Public Education Association assisted the school faculty in building an experience curriculum, in making recreation an integral part of the curriculum, in lengthening the school day for a large proportion of the children to an eight-hour program, and in providing summer camp experience for many children.

Those who have observed the Chelsea School Project have been impressed with the intelligent development of activities centered around services that can be performed by children. The distribution of milk and the management of a school post office, for instance, have been expanded into comprehensive learning activities. The success of the

in-service training program was noteworthy in that a group of traditional teachers have become enthusiastic participants in the activity movement. Finally, the extension of the school day for many of the children has proved a boon to working mothers, has given teachers new insight into the problems of their children by establishing new relationships between teachers and pupils, and has kept large numbers of children off the streets and in a wholesome environment.

Experience with the Chelsea School Project brought out certain needs that must be met if programs with similar objectives are to be successful. The assumption by the teacher of greater responsibility for each pupil makes smaller classes desirable. Clerical assistance must be provided to relieve teachers for teaching functions. Social workers can be of great help in strengthening the community and home channels of communication and aid. The principal or other supervisor must be one who can organize and interpret a community school program so as to gain the active support of all teachers. Volunteers can be helpful in broadening the recreational and health programs in particular. The school plant must adjust to a new role as the center of community recreation throughout the year. And of utmost importance is the participation of *all* community agencies and groups that have a contribution to make—family, religious, civic, health, and social.

While the program of the All Day Neighborhood Schools in New York City has been and still is handicapped by the lack of certain important facilities and personnel and the failure to get the cooperation of all community agencies, its success has been sufficient to lead some educators to refer to them as the "Schools of the Future." The pattern of their development, i.e., private initiative and support, public permission, and finally public acceptance and support, is worthy of study by laymen and educators interested in promoting educational programs that serve the whole child. (See COMMUNITY AND SCHOOL.) R.S.F.

ALL-YEAR SCHOOLS. In contrast to most schools, the all-year school provides an organized program of instruction for an entire calendar year, making no provision for an extended vacation period for all pupils at the same time. Usually the year is divided into

four quarters of twelve weeks each, with attendance required in any three of the quarters. While students may attend all four quarters, they may select any one quarter as a vacation period.

The all-year school, in comparison with the usual school, provides an opportunity for children to engage in worthwhile educational activities under the guidance of adults during the summer months as well as during the other months of the year. This, probably, is the outstanding advantage of the all-year school, although many other advantages are cited by its advocates.

Although it is claimed that under the all-year school plan the cost of education is decreased, the reverse is likely to be true unless pupils attend only three of the quarters and their enrollment is spread approximately equally over the four quarters, and unless teachers are paid the same yearly salaries for twelve months as they are paid for the traditional school year.

The all-year school enables pupils to shorten the period of their education through attending all four quarters of the year. The value of such acceleration for most children is, however, open to serious question.

Under the all-year school plan children are given a greater opportunity to choose when they will or will not attend school during the year. While this may be relatively unimportant, at least it offers the children and their families more freedom of choice than does the practice under the usual plan of required attendance.

In spite of the almost inevitable increase in the total cost of education under the all-year plan, the benefits to be derived from providing an organized program of education for those children who are not cared for adequately by other organized agencies and who are left to seek their own diversions during long periods of time during the summer vacation period may more than compensate for the additional expenditure necessary.

Although the idea of the all-year school is not new, there have been relatively few cities that have operated any part of their school system for all pupils on the four quarter basis. The five cities referred to most frequently in connection with the all-year school are Newark, N. J., Nashville, Tenn., Mason City, Iowa, Alliquippa, Pa., and Ambridge, Pa.

AMBIVALENCE. Coexistence in an individual of two opposite or contradictory emotions, feelings, or ideas. The existence in a child of love and hate for a parent or teacher exemplifies emotional ambivalence. There is considerable disagreement among members of various schools of psychology as to the origin of the hate aspects of ambivalence. Freud originally thought of it as innate and instinctive. Most modern authorities believe that hate develops out of the frustrations of the love impulses which any culture must of necessity show. Thus the child soon learns that the amiable father who takes his son on trips is also the stern magistrate who punishes misdeeds, and the teacher who tells such delightful stories is also the one who reprimands children for being restless.

AMERICAN INDIAN, EDUCATION OF. Various types of schools are available for Indian children. These may be classed in three categories: (a) schools under the direction of the Office of Indian Affairs, including reservation community day schools,

AMERICAN RED CROSS, EDUCATIONAL WORK OF

reservation vocational high schools, and non-reservation vocational boarding schools; (b) mission, private, and state schools with which the Indian Office makes contracts; (c) public schools with which the Indian Office makes contracts either directly, or indirectly through the State Department of Education.

As a whole, Indian education today shows the influence of two somewhat opposing points of view. One assumes that through carefully guarding and expanding basic cultural patterns, supplemented by the development and expansion of the economic resources which the group possesses, a greater degree of security and ultimate satisfaction can be secured. The other point of view is based upon the assumption that a minority group is always in a hazardous position and that as long as it remains as a distinctly separate group there is grave danger that it will be pressed into an inferior social and economic position and held there. It follows from this latter position that amalgamation with the dominant group is the ultimate and desirable goal.

In certain places serious effort is being made to get students to study and understand the economic resources—potentialities and limitations—of their home reservations. In harmony with this emphasis, cultural patterns and native arts and crafts are studied and encouraged. Vocational direction and planning are, to some extent, influenced by this content. Group activities, in conformity with old cultural patterns, are encouraged. As an illustration, some Indian bands, utilizing their land resources, have established large and flourishing cattle herds. Similarly, there are farming associations, arts and crafts associations, marketing cooperatives, and even tribal welfare organizations.

In many areas, however, Indians are widely scattered. These are the groups that show the greater influence of white cultural attitudes and habits. Their children go to the same schools as whites, take the same courses, play the same games, and frequently marry their white classmates.

When viewed from this background, it can be stated that there is no typical educational pattern within the structure of Indian education today. Representative schools, both public and private, can be found which are following one or the other points of view. In-

deed, even among the Indians themselves there is no unanimity of agreement on this issue, among either groups or individuals. But it also needs to be emphasized that this very lack of agreement is in the main wholesome. Eventually, a critical analysis of these different educational processes may have great influence, not only upon Indians and their place in American society, but upon other minority groups and even upon the procedures and basic theory of educational agencies generally. AMERICAN RED CROSS, EDUCATIONAL WORK OF. The entry of the American Red Cross into the field of education dates from 1910. Since then this work has proceeded on an expanding scale to meet the demand of a public which is increasingly aware of the need and value of health and safety education. This work is directed to adults and young people.

Starting initially with a relatively modest effort in first aid, the program today includes swimming and diving, life saving and water safety, home and farm accident prevention, home nursing, nutrition, nurse's aid training, and a number of special courses required for membership in the several Red Cross volunteer service corps.

From the standpoint of numbers, more persons have completed courses in first aid than in all the others combined. In the years since 1910 the Red Cross has built up a system of training instructors so that virtually every one of the 3,755 chapter areas is in a position to provide instruction. For those not having qualified teachers, Red Cross representatives make periodic visits to serve this purpose.

There are three first aid courses: basic, advanced, and instructor's training. The basic course consists of a minimum of 20 hours of instruction and practice, while the advanced

covers 10 hours. The instructor's training course, devoted to developing teaching technique, is of 15 hours' duration and is open to selected persons who have satisfactorily completed basic and advanced courses. Instructors in this course are carefully chosen and specially qualified by the First Aid Service at National Headquarters.

As of June 30, 1942, the Red Cross had issued 6,647,738 certificates of all types for completion of first aid instruction. Of this number 3,610,095 were trained during the year ending on the above date. To achieve this figure the Red Cross expanded its instructors corps from approximately 30,000 on July 1, 1941, to more than 150,000 a year later. The majority of these instructors were trained by the Red Cross, though many represented doctors who volunteered their services.

Water safety instruction was begun by the Red Cross in 1914, and up to June 30, 1942, there had been issued 1,230,459 life saving certificates, each testifying the holder had successfully completed the necessary training to enable him to rescue persons in danger of drowning and knew how to undertake to revive those apparently drowned. Courses in swimming were added to this program in 1930, and by June 30, 1942, 1,674,767 persons had qualified as swimmers. Selection of water safety instructors is on a similar basis as in the First Aid Service.

Each year the Red Cross sponsors a series of national aquatic schools, held in readily accessible centers throughout the country. These provide advanced courses in all aquatic subjects, in first aid, and in accident prevention. Open to everyone qualified for advanced work, these schools are frequented by physical education instructors and others who find them the best means of keeping abreast of developments in their fields and, at the same time, maintaining contacts with colleagues in other parts of the country.

In teaching accident prevention the primary effort is directed toward evoking mental alertness toward the factors causing accidents, and outlining necessary steps for their prevention. Courses in accident prevention are of 9 and 12 hours' duration, the longer one covering farm accidents in addition to those occurring in the home. Certificates for completion are awarded. The instructor's training course is

of 15 hours' duration.

In the larger sense, first aid, swimming and water safety courses are accident prevention courses, for attention of the classroom is ever directed to methods of avoiding all types of mishaps. When first aid classes are held for specific groups, such as steel workers, transportation employees, and others, emphasis is placed upon accidents commonly associated with the industry involved and means of prevention stressed.

The Red Cross inaugurated home nursing instruction in 1914. By June 30, 1942, 1,551,943 persons had successfully completed this course. It covers a minimum of 24 hours and is taught by registered nurses selected by the Red Cross Nursing Service. The course is divided into four principal parts. One covers such subjects as protection against disease, selection of food, and healthful home environment. Another concerns community health and sanitation. The care of mother and baby and of infants through their first year forms the third unit. The fourth teaches what to do when sickness invades the home. The increasing shortage of medical facilities during the war added vital importance to this course, and during the year following Pearl Harbor, monthly enrollment of students averaged just under 100,000. To provide home nursing classes in rural areas where registered nurses may be few, the Red Cross uses itinerant instructors who visit centrally located communities and over a period of six or eight weeks conduct classes in surrounding towns.

The Red Cross Nutrition Service was inaugurated in the early twenties when little attention was paid to this subject. Today, with its background of experience and training, this service is proving of tremendous importance. With food rationing limiting diets and with the need of good nutrition never more pronounced, housewives the country over are learning proper means of feeding their families to maintain health, strength, and mental alertness so they can give their utmost to their work. Nutrition is taught by home economics instructors and others possessing the necessary training, most of whom volunteer their services.

Classes in these subjects are open to all persons, and instruction is offered by a majority of Red Cross chapters. Although many

chapters directly sponsor classes for young people, arrangements have been made in many areas whereby they are offered in schools, either as a regular part of school work or as extracurricular activities.

Instruction for prospective members of the various Red Cross Volunteer Special Services is on a different basis than the foregoing. First of all, members of Volunteer Special Services are required to devote periods of time to Red Cross service, and for that reason many persons are not interested in the work. In the Volunteer Nurse's Aide Corps members agree to serve 150 hours annually for five years following training, which covers 80 hours. Instructors are doctors and nurses, and 35 hours is classroom work, while 45 hours of the training is given on the wards of cooperating hospital under supervision of registered nurses. Upon completing their course nurse's aides, in a sense, become a second pair of hands and an auxiliary mind to the nurse, enabling her to devote herself to duties requiring full professional experience and training.

To qualify for the Red Cross Canteen Corps, members must complete courses in nutrition and canteen administration. This latter takes up problems of mass feeding, sanitation and cleanliness, portable canteens, and other related subjects. Other Red Cross Volunteer Special Services, including the Staff Assistance Corps, Motor Corps, Production Corps, Hospital and Recreation Corps, and Dietician's Aide Corps, have developed special courses of instruction for their prospective members.

In its public education work the Red Cross found it expedient to prepare its own textbooks. The first aid textbook was prepared in cooperation with a committee of doctors, the swimming and diving and the life saving textbooks were prepared in cooperation with nationally prominent swimming coaches, and the Red Cross home nursing textbook with a committee composed of doctors and nurses. The same care was taken with the publication, "Food and Nutrition," and in the preparation of all courses for the Volunteer Special Services.

In addition to providing courses in first aid, life saving and water safety, home nursing and nutrition for young people, the Red Cross reaches boys and girls of school age through

the American Junior Red Cross. This organization was formed in 1917 by proclamation of President Woodrow Wilson to give school children an opportunity to serve with adult members of the Red Cross in World War I. Its activities then, as now, were designed to fit the school curriculum.

Nearly all of the present-day Junior Red Cross activities may be tied in directly with school room work. International and inter-sectional correspondence albums, depicting home territory environments and cultures; the packing of gift boxes for foreign children; service to the blind; and community services are frequently incorporated in the social studies. Other activities, such as production for the armed forces, war relief production, first aid and water safety training, and accident prevention are adaptable to numerous classes in elementary and secondary schools.

Other activities—canteen, nutrition, staff assistance, home nursing and disaster preparedness—are practiced both in and out of school. The process of earning money to buy material to construct articles which are then used by veterans, members of the armed services, or less fortunate children elsewhere, is typical of the broadening opportunities offered members of the American Junior Red Cross.

The program is based on the educational philosophy of "learning by doing." With that end in view national and local Junior Red Cross projects have educational features which, though sometimes indirect, serve their purpose admirably.

AMERICAN SAMOA, EDUCATION IN—See UNITED STATES TERRITORIES AND OUTLYING POSSESSIONS, EDUCATION IN.

AMERICAN YOUTH COMMISSION. The American Youth Commission was organized in September, 1935, by the American

Council on Education to study problems relative to the care and education of American youth from twelve to twenty-five years of age.

The need for the commission arose from the economic and social conditions of American youth, which were accentuated by the depression. Many thousands of youth were roaming the country, destitute and unable to find employment. Other thousands were crowding the high schools of the country, rapidly expanding school enrollments at a time when school budgets were being reduced drastically. In an effort to provide the basic planning necessary to meet this situation, the American Youth Commission was created and was delegated specifically to:

- (a) consider all the needs of American youth and appraise the facilities and resources for serving these needs;
- (b) recommend procedures and programs which seemed to be most effective in solving the problems of youth;
- (c) popularize and promote desirable plans of action through conferences, publications, and demonstrations.

The commission has been primarily concerned with the educational adjustments of youth to the changing social conditions and has been vitally concerned also with matters of health, recreation, crime, vocational adjustments, and other problems closely related to the educational problem.

It has attacked the problems by assembling the research of others on the problems of youth, by organizing conferences to which experts on the various phases of the youth problem were invited, and by carrying on extensive field investigations by its own staff. Among the first of these investigations was the Maryland Youth Survey, the report of which was published in 1938 under the title, *Youth Tell Their Story*. This report revealed that the number of unemployed youth during the depression was probably as large as 4,000,000, a fact later confirmed by the 1937 federal census of unemployment. The findings of the Maryland Youth Survey resulted in a cooperative project, organized in 1938 in four cities and four rural counties, to test community programs of occupational adjustment for youth.

Other major studies by the commission include a survey of youth in the cities of

Muncie, Indiana, and Dallas, Texas; a study of the Civilian Conservation Corps, which also embraced observation of NYA residential projects and work camps being conducted under private auspices; and a study conducted in several centers in the South and North to determine the effect of class and caste restrictions upon the developing personality of Negro youth.

The recommendations of the commission frequently have been implemented by the publication of bulletins and reports, radio broadcasts, conferences, and other techniques. C.S.

AMERICANIZATION. The history of Americanization has moved from a haphazard, and even negative, program of education to one that today is the subject for careful scientific and professional thought; from a frame of reference around the foreign-born only, to one that encompasses the native-born as well; from the narrow confines of naturalization to the broad implications of citizenship.

In the early days of the Republic, little or no thought at all was given to the Americanization problem. Such consideration as was sporadically directed to it, referred solely to local problems growing out of the increasing admissions of immigrants to this country. The native-born, it was assumed, were thoroughly

AMERICANIZATION

Americanized through their heritage, their learnings, their associations, and their life pattern. The foreign-born were welcomed as an answer to an industrial need and because they filled in voids in the labor fields. Their impact on our political and social life was accentuated only when such movements as the Know-Nothing Party bitterly opposed further immigration in the 1850's, or when the Native American Party initiated a wave of violence against the Irish Catholics earlier in our history. Although immigration restrictionist movements flourished throughout these, and later years, the influx of immigrants continued to increase while concepts of Americanization remained dormant.

As the years passed, opposition to the entrance of immigrants, on the basis of potential social and political dangers, grew in intensity. While industrial, labor and sectional groups had initiated these attacks up to the 90's, sociologists found the subject worthy of keen, relevant and close consideration, and gave it growing attention. Studies and reports were submitted asserting that the South-Eastern European immigrants were endangering American institutions, and that their concentration in our cities handicapped the development of any homogeneous growth in this country. This sociological approach focused attention on the specific problem of Americanization. It was, moreover, to be the forerunner of a concentrated attack on all non-Nordic aliens. In later years, this thesis was supplemented by the findings of the Federal Immigration Commission, whose extensive report in 1911 stimulated the interest of social agencies throughout the country in this subject. A very marked schism developed among those interested in the problem of Americanization—a schism that was to express itself in the next quarter century in terms of legislative enactments, increased emphasis on school programs, and a change in the general reaction by the alien in the United States.

With the opening of World War I, the attention devoted to the Americanization movement became more widespread. The loyalties expressed and demonstrated by aliens in the United States toward their native countries awakened us to the futility of the programs and attitudes that had been indulged in under the heading of Americanization. The concept

of hyphenated-Americans was widely attacked in the press. Agencies at once recognized this situation as one demanding attention. Classes in Americanization were organized in schools, settlement houses, factories, and homes. The Federal Bureau of Education and the Naturalization Division of the United States Immigration and Naturalization Service prepared a *Federal Textbook on Citizenship Training* which was distributed free to all accredited schools. Americanization bureaus, which still operate, were organized by statute in many states. Labor groups, factories, Y. M. C. A.'s, and churches joined the schools in this movement. All sought to Americanize quickly the foreign-born in this country. Aside from an inept effort on the part of the Federal agencies to suggest plans, and occasional national and state conferences of interested groups, there was no central direction or program or guidance. Content, method, and approach varied. In general the aim was a mastery of elementary English, American history and civics, and geography. Later some trade subjects were added.

But as the post-war years rolled on, and the depression set in, an anti-alien philosophy, based on the numbers of unemployed in this country, began to make itself increasingly evident. The vast tide of immigrants was attacked as one of the primary causes for the depression, with the consequence that Americanization programs became more and more unpopular. In addition, financial distress and lack of opportunities resulted in a severe drop in class registrations. Social scientists, who refused to accept quick and superficial judgments, began a belated analysis of the Americanization movement; their findings led to many changes in heretofore accepted philosophies and objectives. In place of Americanization, assimilation began to be stressed; soon the emphasis was again transferred to the problem of citizenship training of both the native-born and the foreign-born. For the solution of this problem, responsibility was placed on the schools generally and on adult education specifically.

It became evident that the procedures which had been blindly followed since emphasis had been placed on Americanization, were in part commendable and in part open to criticism. One of the major fallacies lay in treating Americanization as an osmosis-like process;

it was held that unconsciously a spirit of loyalty to, and an understanding of, our institutions would seep in. In its later development, this expressed itself in the "Melting-Pot" theory, in which it was assumed that all alien cultures, philosophies, and mores were fused into the American pattern through naturalization and Americanization. But, at the same time, there existed a very coherent cross-section in this country whose philosophy on the subject was expressed tersely and significantly in the attitude, "We let them in; now let *them* work it out."

The first World War crystallized some of the weaknesses and fallacies in these theories. We realized that stressing the obligation of becoming a naturalized citizen did not necessarily make for loyal American citizens; that the acquisition of a certificate of naturalization might be treated by the alien as an economic advantage rather than as a patriotic fulfillment or as a release from an undesirable classification; that, in themselves, such certificates were no assurance of the addition of interested citizens. Accordingly, efforts were made to supplement courses in *English and Citizenship* with programs involving participation in the American scene by the foreign-born. The *I-Am-an-American Day* became a national function for all new citizens in 1938. Attendance at celebrations, trips to historical places and to seats of government, and public meetings to commemorate their advent into citizenship were adopted in varying degrees. Yet, up to this time, progress in Americanization was still expressed by a numerical index: the number of aliens naturalized. The question had not yet been answered: how to inculcate citizenship, through living, as a sense of oneness with this country.

The solution to this problem was not simple. It was—and to some extent, still is—difficult to assimilate, and establish a feeling of loyalty in a people who were being attacked and against whom discriminations were being practiced. Threats of deportation and of registration were renewed from period to period both in Congress and by private anti-alien groups. Discriminations against the employment of aliens by states and municipalities, by industry, and by labor unions continued to mount. Social distinctions and anti-alien prejudices were in evidence in all forms of human contact and intercourse. The restric-

tive laws, beginning with those of 1882, and continuing through the Literacy Test Law of 1917 and the National Origins Act of 1924, convinced the alien that he was unwelcome. As the result of such attacks and attitudes, the movement toward Americanization suffered.

However, as an offset to this, there came into existence a concurrent program, led by sympathetic welfare agencies and churches, and by groups within the legislative bodies. These groups aimed at developing a sense of self-respect and pride in the alien; they spoke appreciatively in terms of the alien's background, his contributions, his culture, and his eagerness to become an American. Much was made of the 27th Division in World War I because of the international character of the cross-section of its soldiery; later an "All-American Week" was widely celebrated. Earnest counter-attacks were directed against the forces that sought to undo the basic values in Americanization.

These organizations awoke to the fact that the effort to Americanize through the act of naturalization was, by itself, of dubious value. With mere naturalization as the goal, citizenship was looked upon as a matter of material value, rather than as a privilege founded on loyalty and understanding. Aliens were advised to "get their papers" because of the benefits they would gain. Stress was laid on rights, rather than on obligations and duties. In teaching citizenship, too much emphasis was placed on the science of government, and too little stress on the development of a spiritual unity with our institutions, our backgrounds, and our national life. Not enough thought had been given to the thesis that if real Americanization was to take place, it must come through a feeling rich in American understanding—one that would be in harmony with our political philosophies and loyal to our objectives. We overlooked the fact that nationality is in essence a spiritual thing.

There were those who, like Prof. Fairchild, held that "traits of nationality will not combine, and so, nationalities as a whole cannot be mixed". Americanization was not to be interpreted as a sort of religious conversion. On the contrary, it called for an evolutionary synthesis of racial, cultural, and economic factors. Some assailed the theory of Amer-

icanization—and later assimilation—as an error in that it assumed that foreign cultures could be absorbed or fused; they maintained—and this school has had a growing following—that cultural pluralism, in which independent cultures exist side by side, and not the fusion of cultures, was basic to any real program of Americanization. They urged that the foreign-born should not be encouraged to forget their background but rather that they be urged to incorporate its best features into the American pattern.

Out of these efforts to arrive at a sound program of Americanization has come a new concept. Social scientists and educators recognize the need for a new directional force in this movement. It has become obvious that a single emphasis, in Americanization, is a limited and inadequate approach. It has been recognized that mere birth in this country may automatically confer citizenship on a person, but that it does not necessarily indoctrinate him for sound American citizenship.

As a result, adult education has today taken up the cudgels for Americanization through its program of citizenship training for all. The schools, the private and public agencies, the army and the navy are evolving lessons for the classroom and over the air, designed to Americanize Americans. What began, just before the turn of the century, as a well-meant but haphazard drive toward the Americanization of the foreign-born, has developed into an enriched and purposeful program for the citizenship training of young and old, that has sought to attain, through understanding and intelligent acceptance, a faith in our democracy making for political and social homogeneity. ANALOGIES TESTS — See OBJECTIVE TESTS AND EXAMINATIONS.

ANALYTIC METHOD. Analysis is a general term referring to a number of methods of investigation which have the common characteristic of systematically considering some type of data in detail. Most commonly it means separation of an object into its parts and consideration of their relations to one another and to the whole.

In reading instruction, those methods of teaching beginners which start with comparatively large units and work down to smaller units are called analytic methods; they include the story method, the sentence method, and the word method. The alphabet method and phonic and phonetic methods, which start with parts and build up to the whole, are in contrast called synthetic methods. (See READING, METHODS OF TEACHING.)

In educational research, an analytic method is one which breaks a large problem down into a number of specific issues which are more amenable to carefully controlled investigation. The classification, tabulation, and statistical manipulation of data so as to discover important facts and relationships is another type of research activity for which the term analysis is used. (See RESEARCH, EDUCATIONAL.) A.J.H.

ANECDOTAL BEHAVIOR JOURNAL. The Anecdotal Behavior Journal is that part of the pupil's total cumulative record, sometimes called Behavior Journal, which is made up of the chronological recording of significant items of conducts, episodes in the life of the pupil, word pictures of the child in action, or any narrative of events in which the pupil takes such a part as to reveal something which may be significant about his personality.

Anecdotal records may be of three kinds: (1) simple narratives of the child's actual behavior responses or events in which he takes a significant part; e.g., *Nov. 16. George took charge of assembly today with poise.* (2) record of the observation with an interpretation; e.g., *Dec. 4. George did part of a motor experiment today in which the instructions specifically stated that the instructor must be*

present. George sought the aid of a student instead. When things went wrong he pulled the switch promptly and avoided trouble. Interpretation: It should be noted that he had the presence of mind to save the situation. He goes ahead by himself too much without regard to instructions. (3) the anecdote accompanied by recommendations either to the student or some supervising officer; e.g., March 12. When called on today Betty acquitted herself very well but I do not recall that she ever volunteered in my class. She seems friendly and responsive when approached. I know she has unusual native ability and I do not understand why she does not do more and better work. Recommendation: I recommend that she be interviewed by the supervisor.

Anecdotes carefully recorded over a period of time, with entries made by different persons observing the pupil, give an objective picture of the personality of the child in action. They should be of special use to the teacher, guidance officer, or other school officials, but should be kept as confidential material.

The general purposes served by anecdotal records are: (1) as data needed for increased faculty understanding and diagnostic material for the study of the total personality; (2) as data needed for counselling; (3) as data for increased understanding of the pupil outside of school; (4) as material for curriculum design and control; (5) as evidence for evaluating the success of a program for an individual child; (6) as qualitative data to supplement quantitative; (7) as illustrative material for textbooks and other documents essential to professional progress; and (8) as an indication of the philosophy of the school using them, e.g., helping pupils develop a functioning personality pattern.

Though many educators and psychologists agree that the anecdotal behavior journal is a useful means of assembling personal data concerning various students—data that may be of great value in guidance work—many objections have been raised to the use of the anecdotal behavior journal. First, since it is the teacher who usually determines which incidents merit recording, the impression created by a reading of the anecdotal record may reflect the teacher's opinion of the student as much as it does the student's behavior patterns. Thus, the teacher who regards a

particular student as uncooperative may record every instance of his failure to cooperate even though the teacher may overlook similar instances in which other students are at fault. Despite the apparent emphasis on factual accuracy, the anecdotal behavior record may be no more objective than is the traditional rating in conduct or behavior which is recorded at the end of the term. Second, the value of the anecdotal behavior record varies with the significance of the incidents that are recorded. If the teacher has little insight into child psychology or only an inadequate understanding of the use for which the material is intended, the anecdotal behavior journal may be nothing more than a bulky collection of petty and irrelevant incidents. Third, when classes are large, the labor and time consumed in the teacher's writing of the incidents may lead either to unwarranted inroads on the teacher's time with the consequent neglect of other activities that may be more valuable, or to the attitude that the recording of these incidents is a chore to be performed as quickly as possible. These objections indicate that the introduction of anecdotal behavior journals is likely to be of little value unless the teachers who are to assemble this information are convinced of the need and understand the purposes to be served.

Since the anecdotal behavior records are qualitative in nature, the user must depend on his own knowledge of psychology and psychiatry to interpret them. A manual of directions has been prepared to assist schools in introducing anecdotal records into their personnel practices. (See CHARACTER EDUCATION; GUIDANCE; MENTAL HYGIENE; PERSONALITY.)

ANNOYERS AND SATISFIERS.

Thorndike (*q.v.*) defines *annoyers* and *satisfiers* as after-effects of a response. They are rewards, punishments, failures, successes,

pleasantnesses, and unpleasantnesses to the learner in terms of his wants, interests, and attitudes. Whether they occur fortuitously, the learner having no expectation of receiving them when making his response, or whether they are the expectation for which the animal or person is striving, seems to matter little, according to Thorndike. In either case there will be a tendency to repeat the action which has brought the satisfier. The effect of annoyers is very much weaker than that of satisfiers; success and reward are much more potent than punishment and failure. In some instances, an annoyer may even strengthen, rather than weaken the connection to which it is applied. Though Thorndike connects annoyingness and satisfyingness with wants and interests, the interest need not be in the learning which is undertaken. Annoyers and satisfiers act almost equally well, according to Thorndike, whether they arise intrinsically from the activity, or whether they are added as extrinsic motivations. Practically all of Thorndike's work with human beings dealt with the memorization of facts, poetry, and false statements, which may be the reason for his conclusion regarding extrinsic and intrinsic satisfaction. Moreover, where intrinsic satisfyingness was clearly greater with one kind of material than with another, that material was learned more easily by Thorndike's subjects.

Thorndike's later work on satisfiers and annoyers modified his famous "law of effect" sufficiently so that it became much more acceptable to some who had radically criticized it. It became clear that "effect" was not meant to be synonymous with "affect" or hedonistic tone, and that though the description of the learning act was oriented in terms of after-effects rather than in terms of purpose and goal, want and purpose were, nevertheless, considered basic to the process. (See LEARNING.) B.B.F.

ANTIOCH PLAN. "The Antioch Plan" of education—the cooperative work-and-study plan whereby students alternate periods of study on campus with periods of regular work for pay in industries and professions off campus—was started at the University of Cincinnati in 1905 for its engineering students. In 1920, President Arthur E. Morgan applied the plan to all students in all departments at Antioch, thereby for the first time using the plan for liberal arts as well as technical students. Since 1920 the plan has been adopted in many American colleges and in some foreign countries, notably Russia.

In the plan, two students of comparable maturity and ability hold one job, alternating between college study and the job at regular intervals. At Antioch the shift takes place at quarter intervals of 12 weeks. Some 300 employers in some 22 states cooperate annually with the college in providing educational and work opportunities for the students. In some cooperative colleges, the plan is used primarily to give self-support to the students. At Antioch and others, that purpose is only incidental. The latter colleges seek to give a well-rounded and a more realistic education through a combination of a general education program and job placement.

Possible disadvantages of the plan include interrupted study periods, the strain upon students who are not superior both mentally and physically, and the waste of time for students who already have a realistic understanding of the workaday world and an adjustment to it. The advantages of the plan are apparent: the broadened horizons and personal development from the interplay of general education with work in a variety of environments; the close association with many students working periodically in many different occupations; vocational education of the most practical sort; experience while still in college which facilitates adjustment to one's life work after leaving college; and the elimination of many adolescent frills from campus life. ANTONYM TEST — See OBJECTIVE TESTS AND EXAMINATIONS.

APPERCEPTION. The term *apperception*, less used now than formerly, usually refers to the relating of what is being presented to the senses with what has previously been experienced—the understanding of the new in terms of the old. Leibnitz used *perception* to denote the passive reception of sensory data (equivalent to modern *sensation*) and *apperception* to denote the understanding of what is sensed in terms of its causes and relations, much as the term “perception” is now used. Kant, in his use of *apperception*, stressed the characteristics imposed upon sense data by the nature of the mind itself. Herbart, emphasizing the assimilation of sense data to ideas already present in the mind, used the term *apperceptive mass* to denote ideas already in the mind to which the new material is assimilated.

The principle of apperception in educational method, as formulated and developed by Herbart, is based upon the psychological law that the nature of the learning response depends upon the past experience and present frame of mind of the learner as well as upon the nature of the stimulation. As a principle of procedure for the teacher, this means that stimuli must be presented that are adapted to the experience and mental set of the pupils, or else the pupils must be given the experience and put in the right frame of mind before the stimuli are presented. In other words, learning must proceed from the known to the unknown.

This principle is more often designated today as the *principle of preparation and mental set*, or the *law of readiness*, or the *principle of reference to experience*. Although first formulated psychologically by the Herbartians, the principle was applied by the great teachers of earlier times, particularly by Jesus who used it most effectively in His parables. (See HERBART.) E.H.W.

APPRECIATION. An *appreciation* is a product of learning which has value in terms of feeling. It is the personal value, the worth, the satisfaction one gets from experiencing the world of things about him. An appreciation connotes an emotional, as opposed to a purely intellectual, grasp; one may have technical knowledge and understanding of a phase of his environment and yet have no appreciation of it. The essence of appreciation is feeling or emotional warmth; it is the desire to relive a previous experience or have a similar one that is emotionally stimulating.

Within recent times this phase of education has received more and more attention. It is realized that much is lost in our schools if pupils are engaged solely in storing up information and do not learn to appreciate the beautiful and artistic in life. Since there is a close relationship between appreciation and behavior, the development of appreciations should influence one's activities during leisure time—his selection of literature, his choice of radio programs, his preference for musical selections, etc. It is difficult to screen out any of the emotional learnings that influence conduct—such as interests, attitudes, and ideals—but it is safe to maintain that appreciations are important in themselves and as part of the whole spiritual side of man and his worth to society.

To the person trained in color harmony, the colors in the living room must not clash; to a trained musician, the sound must produce harmony. These elements of harmony in music and colors, balance and equilibrium in art, rhythm in motion, and symmetry in forms and shapes are the æsthetic patterns which conform to the highest conceptions of the arts, and are probably necessary for appreciation to those trained along these lines; appreciations which have reached high levels of attainment cannot drop to lower levels readily or at will.

In developing appreciations the apperceptive basis should receive first consideration. The pupil can appreciate only within the limits of his experiential background; he must include himself in the appreciation being developed; his experiences are tied in or associated with the development. Thus the city child who has had no taste of country life may see little that is appealing in a story dealing with the sights and sounds so familiar

to a country child. Secondly, understanding is necessary. This is the cognitive or knowing element, and it is this insight which comes early in appreciation formation. To realize how much understanding contributes to the growth of appreciation one has only to compare the reactions of the child who listens to Tchaikowsky's *Nutcracker Suite* after hearing the story with that of another who listens without such preparation. Thirdly, association with the emotions produces the appeal, the value, and the satisfaction of the learning experience. During an appreciation lesson the teacher's personality, the other pupils, and the environmental factors should be conducive to growth of the appreciation. No teacher can force children to appreciate—he can only bring the right influences to bear. Fourthly, pupils should be given opportunities to be active participants in the learning activities leading to the inculcation of appreciations. Their choices of selections in reading and literature should be respected; their ideas should be solicited; and their efforts praised. Development of appreciations is gradual and the instructor should remember that it grows in terms of years, not of class periods. Fifthly, measurement of appreciations by traditional methods is not recommended as a general procedure. Such tests may measure form and fact rather than genuine feeling and fervor. A pupil can memorize long lists of names of composers and compositions as unemotionally as he learns the spelling of unrelated words. It is almost as futile to measure musical appreciation by asking pupil to identify composers as it would be to measure his appreciation of literature by testing his ability to spell the words which authors use.

Evaluation, by means of objective tests, of growth in ability to appreciate has generally been confined to some kind of written response requiring degrees of discrimination. In prose and poetry several selections of varying degrees of worth are included in the test and the examinee is required to rate the selections in descending order of æsthetic value. In many instances the poem or prose selections deal with the same idea, but the original production by the poet or author is changed and reworded so as to produce selections of varying degrees of merit. In music the same general technique prevails. If the original masterpiece is chosen by the child as the

best, then he shows that he has high appreciation; if the most distorted selection is chosen, it shows the lowest degree of the ability to appreciate. Another kind of measuring device is the questionnaire. A series of questions is given, say about literature, by which the pupil indicates whether he has read any other books similar to the particular one studied; or whether he has read at all during his leisure time. The assumption underlying the use of this type of test is that those who know most about books are those who like reading best and who appreciate literature most.

In addition to the so-called formal tests, a number of informal ways of determining a pupil's appreciation may be utilized by the alert teacher; he may observe the pupil's attitude toward subjects, the number and kinds of books and magazines he reads, his responses in class, his choice of radio programs, of topics in written work, of movies, and his hobbies and leisure time activities. (See ART EDUCATION; ENGLISH, TEACHING OF; MUSIC APPRECIATION.) F.A.B.

APPRENTICE TEACHER. An apprentice teacher is usually regarded as one who has completed the formal requirements for teaching and who is engaged in his first year of actual teaching. Generally, an apprentice teacher is regarded as on probation pending satisfactory completion of the first year's experience, often under some sort of special supervision. Some institutions use the term *apprentice* or *cadet* to apply to the status of *student teacher*. (See TEACHER EDUCATION.) R.F.B.

APPRENTICESHIP EDUCATION. Many Federal, State, and local leaders in vocational education use the terms "apprenticeship training" and "apprenticeship education" interchangeably. The basic feature of apprenticeship is teaching a learner "on the job," and supplementing his occupational experience and training with "related instruction" (*q.v.*). The latter includes related

mathematics, science, drafting, and trade theory. At least four hours per week should be given to carefully planned related instruction.

The program of apprenticeship education should conform to accepted standards and should be given in accordance with plans approved by representative apprenticeship advisory committees on which labor and employers are represented equally.

Apprenticeship training should involve the cooperation of at least three agencies: the schools, labor, and the State employment service. By written agreement between the U. S. Office of Education and the U. S. Department of Labor, the U. S. Office of Education is responsible for the training, and the U. S. Department of Labor for safety, health, hours of work, compensation, and other working conditions. The Employment Service has responsibility for registering, classifying, and assisting workers in securing suitable employment.

It has been estimated that in 1941 the United States had 125,000 apprentices for skilled crafts, and that it urgently needs twelve times that many. (See VOCATIONAL EDUCATION.)

APTITUDE. It is becoming general to apply the term *aptitude* to the degree with which the present characteristics of a person are symptomatic of his ability to acquire, with training, certain specified knowledges or skills, rather than to define aptitude as some hypothetical innate faculty or power. The term implies that if persons who formed a random sample of the population began training or working at some specified task under similar conditions some would be more successful than others. It does not imply that if two persons are to be compared as to the degree of aptitude they possess, the characteristics chosen for observation must be one with regard to which neither has had an advantage in training.

Aptitude tests are similar to intelligence

tests in that they forecast or predict. Indeed, intelligence tests are often called general aptitude tests or mental aptitude tests. Aptitude tests as a whole, however, ignore many of the theoretical assumptions upon which intelligence tests are built. Aptitude tests are planned in terms of a definite purpose rather than in terms of differences among people. It is that purpose which determines what shall constitute the "test" of the aptitude. If the purpose is to determine whether *A* will make a good pilot if he is given the army aviation training, *A* is tested in terms of what it is thought will be, or more accurately, what has proven to be, predictive of aviation success. Aptitude tests are given at the time when it is necessary to make such a prediction. A person is not expected to obtain the same score on the same aptitude test throughout his life. In most instances the aptitude testing devices generally used almost preclude such a possibility.

Various measures for judging aptitudes are in use; some formal, some informal. Interest, initial ability, and incidental learning have all been widely used as signs of aptitude. In many schools where it is desired to take individual aptitudes into consideration, the pupils are provided with a rich environment and a wide range of material for free periods of study and use as they wish. The pupil's interest as defined by what he engages in, and the quality of his performances in this area are interpreted as revealing to observing teachers the aptitudes which it would be valuable to increase with special training.

Poor beginning performance has frequently been used in high school and college to eliminate from future training in a specific subject all those who lack sufficient aptitude for success. While very poor beginning performance is probably a better indicator of failure than excellent beginning performance is of high success, this technique often involves much error, particularly if there is too short a training period before judgment is made. Curves of learning vary from individual to individual, thus making it difficult on the basis of the beginning of the curve to predict the remainder with accuracy. Moreover, the cause of the poor start may be a deficiency in prerequisite knowledge or skill which can be attained by study. His poor beginning

means that the student is not ready to undertake the training now, rather than that he will never succeed. Reading aptitude tests are usually, though not always, termed reading readiness tests for this very reason. A period of reading readiness training is inserted, where necessary, between the time the test is given and the time specific reading teaching is begun.

Standardized aptitude tests use devices similar to those employed informally. The Stenquist Mechanical Aptitude Test and some of the army aptitude tests, for example, have picture sections which test incidental information about mechanics and mechanical objects. Other aptitude tests, such as reading readiness tests, foreign language prognosis tests, mathematical prognosis tests, Stenquist Mechanical Assembly Test, the MacQuarrie Test for Mechanical Ability, test the subject on the various functions involved in the undertaking in question. For example, being able to choose out of four words the two that are alike, and being able to select the correct pronunciation out of four different pronunciations given by the examiner for the same word are two tests of reading readiness. Being able, given some vocabulary and grammatical rules of an artificial language, to translate a passage in that language is one test of foreign language prognosis; given all the part of simple tools to put them together into a working tool is one test of mechanical aptitude.

Some aptitude tests appear to differ little from ability or achievement tests. There is, however, a fundamental difference between these two types of tests. The achievement test measures what the person can do now; the aptitude test is not valid unless it predicts future success. Aptitude tests are therefore empirically validated by means of correlating performance on the test with performance after training, or on the job. Unfortunately, even many of the widely used aptitude tests have only a low validity. Taken together with other factors, however, they often become useful instruments for guidance.

One other fact to be noted is that aptitude tests are more valid in predicting how successful the person will be in acquiring the ability, provided of course that he undertakes the training, than they are in predicting vocational success. Too many factors are

involved in vocational success to allow aptitude tests to be sufficiently predictive. (See GUIDANCE; PREDICTION OF SUCCESS; PROGNOSTIC TEST.)

ARCHITECTURAL EDUCATION.

Architectural education today presents a confused picture, reflecting the status of the architectural profession, but by 1942 the necessity for a creative basis for architecture as opposed to an eclectic approach was recognized. The grounding of students in the "orders" of architecture had been generally discarded, but the question of what to substitute as a basis of training had not been answered. The growing importance of the mechanical or operating elements of buildings, increased use of prefabrication, a growing conviction that architecture starts with site and city planning—all these increase the knowledge the architect should master. The dwindling practice of the small office, the mushroom growth of the large factory-like office, the architect working as an employee of industry, and the extension of governmental agencies which practice architecture make it difficult for the schools to present a single educational objective. Moreover, the number of states requiring an examination to obtain a license to engage in independent practice may present a threat to education, because pointing toward these examinations may freeze material and methods of teaching.

There are three broad types of educational methods employed today—the apprentice, case, and interne. The apprentice type is the oldest, probably coming from the feudal guilds. This method worked best when the student helped a strong practitioner who used few materials and was intimately connected with the entire process. The multiplication of materials and the complexity of mechanical parts requiring a systematic study of sciences are arguments against this type of train-

ing. At Frank Lloyd Wright's Taliesin Fellowship this system of learning by doing is followed, although Wright himself had formal engineering training.

The system of following a strong master is still reflected in many schools using the case method in which the design staffs are headed by outstanding practitioners. There is a growing agreement in almost all schools that faculty members should engage in practical work. The case method, followed by almost all schools, was developed in the *École des Beaux Arts* in Paris and has since been successfully adapted to teaching in other fields, notably law. Architecture is conceived as the synthesis of many factors, and assumed problems of varying degrees of reality are invented for the student to solve. Unfortunately, the original problems were built around a vocabulary of classical elements and rules of proportion which stigmatized the whole procedure even though subsequent *projets* threw off these limitations. Today's problems in all schools are based on increasingly realistic limitations of site and factual data. Here in America the Beaux Arts Institute of Design still carries on, although the major number of the affiliated schools for which it formerly supplied problems to be competitively judged have resigned. It is worth noting that lately a prejudice against competition in favor of cooperative work has grown in the minds of many students, although practicing architects agitate for more competitions as a means of obtaining commissions. The Beaux Arts Institute still fulfills a need, issuing a hundred programs a year and numbering some of the most distinguished American architects on its active committee.

Most schools recommend a broad general background in Liberal Arts and Sciences before the undertaking of professional study, and require one year of their five-year course in this type of work. All agree more time is desirable.

In the preliminary stage of creative training may experiments are being tried. Some schools stress actual contact with materials: having students lay brick, do carpenter work, run testing machines, etc. Some have had classes build a small house; others rely on exercises in abstract design. All agree that there must be a serious attempt to bridge the gap between the design on paper and mate-

rial construction.

Drafting room practice in design is augmented by lecture and laboratory courses covering graphics, freehand drawing, history, mathematics, construction or engineering, professional practice, and theory. At Yale the material presented in these service courses is scheduled at a time when it will best integrate with the subject of the design projects.

Pratt Institute began an experiment in interne teaching in which advanced students under the supervision of their instructors undertake actual commissions of a size or nature which would be unprofitable to established practitioners. This was meant to bring into the school realistic problems and parallel the free service offered in medical clinics on the theory that, if but a small fraction of American building is architect-designed, some effort should be made to extend this service to the community.

The problem of student guidance between graduation and the time he has acquired sufficient experience to practice has not been well solved. Most schools require their students to work for an architect or builder during a part of their holidays; some suggest an interim year spent in this manner. The American Institute of Architects attempted a system of having their members advise young men in their post-school years.

Foreign travel is still a recognized part of the thorough training of an architect. Many schools have fellowships granted for this purpose. There are also open fellowships for general study and travel, among them the Paris and Rome Prizes for study in those cities and travel in Europe. In recent years students have been more influenced by northern Europe than by Greece and Rome.

Schools of architecture are generally part of a larger institution, less than a tenth being independent schools, a quarter being units of fine or applied arts groups, and the remainder being units of engineering groups, awarding degrees in architecture as well as architectural engineering.

More and more schools are presenting material on city and regional planning. The future will probably see an increased number of large-scale planning projects, and at the present time there are too few professional planners. Two schools are offering courses leading to a bachelor's degree in planning.

ARCHITECTURE, SCHOOL

For the most part there is a wide divergence of opinion both as to the subjects to be taught and where to place the emphasis in this all-important field, which calls for a knowledge of law, sympathy for sociology, the precision of the engineer, and the tact of the politician, as well as the design skill of the architect.

ARCHITECTURE, SCHOOL. Changes in school organization resulting from a broader concept of the educational program have been accompanied by other changes in keeping with the newer educational psychology and philosophy. Noteworthy among such concomitant changes are the changes in architecture. The school plant generally reflects the attitude of the people toward education. The school plant described by Barnard as "intended to hinder and not promote, to defeat and not to perfect the work which was to be carried on" is being replaced by the plant designed and equipped especially for the type of work to be done. In other words, the school plant is now considered a service agent subordinate to the general purpose of education. This idea is called the *functional conception of the school plant*. The word *functional* is defined as "performing or serving a function, as a useful purpose or special activity; designed, developed, considered with reference to a function or to functioning."

In the development of a functional school plant educational planning precedes planning of the plant. The school today is considered as an agency to meet the educational needs of the pupils and of the community in which they live. School buildings are conceived of as factors in facilitating the instruction of the child and in satisfying other educational and social needs of the community. According to this philosophy the nature of the school architecture is influenced by the objectives of education, the type of curricu-

lum, the plan of school organization, the number, ages, and educational levels of the pupils, the size of classes, the equipment, the methods of teaching, and the use of the plant for community needs.

There is a definite tendency to consider the school as an institution within a community, a kind of community workshop, a focal point of community welfare, a place where school children are happy and where they learn not only the three R's but also abilities, skills, and attitudes in many fields. The school is a place where adults as well as children go to find help in solving their problems, and where they participate in community life. The school is a place where democratic living attains its highest purpose. This newer conception of the place of the school in the community has influenced the planning of school plants as well as the architectural designs of school buildings. The tendency is in the direction of cooperative planning in which the school architect, teachers, pupils, principals, janitors, and patrons, as well as the superintendent, participate. Every school and community has its own peculiar problems. The school plant is cooperatively planned to provide the best possible aid in the solution to educational problems.

The following factors should be considered in selecting a school site: the service which the school is to render as part of the community's total educational program, the geographic center, the population and population trends, the accessibility to streets or roads, the size of the site, the environment, the drainage, and the nature of the soil. It should be remembered that playgrounds are as important a part of the educational plant as the buildings and that healthful and wholesome environment is essential. Any site must be selected so as to fit properly into the total building program of the community.

There is a tendency away from the "monumental" conception of school buildings toward simple architectural plans, attractive and dignified but not imposing or ornamental. Exteriors are simple in line and in ornamentation and depend for their beauty on proper massing, proportion, materials, and harmony of color. Buildings are being designed for the particular purpose for which they are used, yet they possess flexibility and adaptability so that they may be adjusted to

meet the needs of a dynamic school program.

In the planning of new school buildings there is an increasing emphasis on provisions for the safety, health, and comfort of pupils and teachers; larger classrooms, good ventilation, proper lighting, teachers' rooms, and adequate storage space are being provided. More attention is being given to housekeeping problems in selection of construction materials, in provision of sink rooms, electric outlets, and hot water, and in elimination of dust-catchers.

The architectural design and shape of school buildings should fit into the environment so as to present a satisfactory appearance and should at the same time provide elasticity to permit expansion without destroying the beauty and symmetry. Two types of plans for exterior outline for school buildings are used, the *open* and the *closed*. The open plans are usually similar in form to letters of the alphabet. Buildings in T, H, E, U, I, and Y, or similar shapes are frequently recommended. The closed plans are the solid rectangle, the hollow rectangle, and the rectangle with interior courts and auditorium.

With respect to safety features the American Institute of Architects has grouped buildings under five types as follows:

Type A—A building constructed entirely of fire resistive materials, including its roof, windows, doors, floors, and finish.

Type B—A building of fire resistive construction in its walls, floors, stairways, and ceilings, but with wood finish, wood or composition floor surface, and wood roof construction over fire resistive ceiling.

Type C—A building with masonry walls, fire resistive corridors and stairways, but with ordinary construction otherwise, i.e., combustible floor, partitions, roofs, and finish.

Type D—A building with masonry walls, but otherwise ordinary or joist construction and wood finish.

Type E—A frame building constructed with wood above foundation, with or without slate or other semi-fireproof material on roof. (See BUILDINGS, SCHOOL.)

AREAS OF LIVING. In curriculum development an area of living is defined as a group of related life activities set up for convenience in curricular planning and organization. Areas of living are derived from an analysis of activities carried on by pupils. The broad categories of such an analysis become the centers around which learning activities are organized.

Curriculum workers have turned to sociologists, anthropologists, economists, and other research workers in an effort to find those aspects of life that should be taken into consideration in organizing and developing a curriculum. A number of state and city curriculum programs give consideration to these studies as a basis for the scope of the curriculum.

Frederick, following an analysis of thirty-eight classifications of human activities, derived the following major areas of living:

(1) Protecting life and health; (2) Living in and improving the home; (3) Conserving and improving material conditions; (4) Cooperating in social and civic action; (5) Getting a living; (6) Securing an education; (7) Expressing religious impulses; (8) Enjoying and expressing beauty; (9) Engaging in recreation.

Harap recommended the following social functions of the curriculum as a basis of his studies:

(1) Living in the home; (2) Citizenship; (3) Organized group life; (4) Communication; (5) Transportation; (6) Production; (7) Consumption; (8) Leisure.

The Commission on Secondary School Curriculum of the Progressive Education Association based the scope of the curriculum on the needs of pupils, as indicated in the following areas of living:

(1) Personal living; (2) Immediate personal-social relationships; (3) Social-civic relationships; (4) Economic relationships.

Analyses such as these assist the curriculum maker in gaining orientation as to the scope of the curriculum. If the curriculum is to

meet the needs of young people it must take into consideration important social functions.

The formulation of such categories of learning is motivated by an effort to apply the findings and theories in organismic psychology and cultural anthropology. Those who favor the use of areas of learning believe that the present subject organization does not make it possible to present activities and experiences on a functional basis. One of the problems faced by such classifications is that the categories overlap. On the other hand, the studies of areas of living have done much to bring about reorientation of the curriculum in terms of functional living.

The use that has been made of "areas of living" analyses in curriculum construction is more from the point of view of gaining orientation to kinds of activities which should be set up in the curriculum than in developing a new plan for curriculum organization. The area-of-living technique has influenced the selection and organization of units and has given direction to curriculum thinking. The questions which the curriculum worker asks concerning the use of areas of living are, for example: "Does the division of subject matter and activities into areas parallel the kinds of experiences which children have, or are they based on adult experience?" "Can the broad areas be developed into learning units?" "Is the area-of-living organization meaningful to children?" "Is it possible, through the use of areas of living, to present the well-balanced sampling of life activities?"

In a curriculum organized around areas of living, conventional subject matter is introduced, not in a stated time schedule or program, but as it is needed in the study of aspects of living, or in the solution of a problem.

In a curriculum organized on such a plan, the "skills and drills" would come, for the most part, at the point in which these "skills and drills" contribute to the solution of a problem. On the other hand, such an organization would not preclude a developmental or remedial program based on class, group, or individual needs. Organized subject matter might also very appropriately play a part in a synthesis following a study of a series of related problems. Such a presentation, however, would be for the purpose of orienting pupils to knowledge, facts, and problems, rather than for an isolated presentation. The

general curriculum program organized on this basis in no way precludes the study of a subject such as algebra by those who desire to study an organized field. (See CURRICULUM.)

ARGENTINA, EDUCATION IN. Many influences, both foreign and domestic, have left their mark on education in Argentina. The lasting effect of three centuries of Spanish domination as against but a century and a quarter of independent life, for instance, may be largely responsible for centralized government control and the general lack of community initiative in education. On the other hand, French liberalism of the seventeenth century and the more recent influence of the United States have influenced the structure of education, especially on the elementary level, and the cultural and social direction of educational aims.

The government of Argentina is a federation of states and territories each with the right of a good deal of educational autonomy. However, the neglect of the majority of states to assume these rights, due in part to financial inability, has led to greater Federal government initiative and control. As a result, the Federal government has been called upon to administer substantial federal aid in school funds, construction of buildings, foundation of schools, appointment of teachers, and establishment of medical and social welfare aid. Even though there is hardly a school without its association of parents, neighbors, and teachers, community interest in schools is largely lacking in positive social action.

The influence of Domingo Faustino Sarmiento (*q.v.*) was the driving force behind the basic educational law of Argentina (Ley de Educación Común, No. 1420, June 4, 1884). This law established the principle of free, compulsory, lay education, without prejudice to the teaching of religion in the

schools after school hours. This law, in addition, earmarked certain resources and incomes for education. However, since Sarmiento's time governments have carried out this last provision of the law less and less. In fact, there has been a tendency for each political regime to influence education in its own way, a tendency which sometimes militates both against lasting stability and against progress based on sound experimentation.

The three divisions of education—primary, secondary, and higher—are administered separately. In this respect the system differs markedly from that of the United States, in which the primary and secondary schools are generally directed and administered as a unit.

In all three divisions the country spends annually about 330,000,000 pesos, which in the year 1942 represented approximately 20 per cent of public expenditures.

Elementary Education. By virtue of constitutional articles, the educational law of 1884, and subsequent national laws, there exists, along general lines, uniformity throughout the country in a minimum program of principles of elementary school organization, administration, support, etc. Education is compulsory up to the age of 14, co-educational only up to the third grade, free up to the age of 14. Assistance in materials, clothing, food, medical and dental service, is given to the poor children, generally through federally subsidized *Sociedades Cooperadores* (Cooperative Associations) and the *Comisión Nacional de Ayuda Escolar* (National Commission for School Aid). In 1942 there were 723 Cooperative Associations whose aid reached 139,600 children (in 1938, when this work was begun, only 27,759 children received aid). The 1942 budget for food and clothing alone of the National Commission for School Aid was \$5,854,000 (national currency).

Even though the states and territories enjoy educational autonomy, it has been found necessary for the Federal Government, with permission of the states and territories concerned, to offer federal aid beyond the stipulation of the constitution. For instance, in 1905, the Federal government, in order to combat extensive illiteracy, was authorized to establish, direct, and maintain four-grade rural schools to teach reading and writing.

By the end of 1941 there were 4,130 such schools with 14,119 teachers and 457,951 students.

Religious education is permitted in schools only before or after school hours, to be taught by ministers or other persons authorized by the different religions. In general, little use is made of this right as it is not convenient for those interested to teach outside of school hours.

The federal district has pioneered in pre-school education; by 1942 it had established ten kindergartens with an enrollment of 1,139 students.

The elementary school consists of six grades which take seven years because of the division of the first grade into lower and upper grades. In general Argentinian schools are smaller than schools in the United States, even in urban centers. In the Federal District (Buenos Aires) for instance, the average elementary school has 500 students.

The practice of saving in the schools was made compulsory by a national law of 1914. One class each week must be devoted to teaching the concept and advantages of saving.

Federal control of education is distributed among the following: *Consejo Nacional de Educación* (National Council of Education); the *Ministerio de Justicia e Instrucción Pública* (Ministry of Justice and Public Instruction); and, in financial matters, the *Ministerio de Hacienda* (Treasury) and the National Congress.

The agencies exercising local control and administration vary considerably in the several states and territories. In some provinces there are *Consejos Escolares* (School Councils) elected by the people. In the Federal Capital on the other hand the *Consejo Nacional de Educación* appoints 20 *Consejos Escolares de Distrito* for a period of two years. In the ten national territories the *Consejos Escolares* established by law in 1930 have been done away with in favor of various kinds of appointed technical and administrative officials and commissions.

For the training of teachers the establishment of normal schools was begun in 1870 by action of Sarmiento. In 1942 there were 90 official normal schools with 25,707 students. Almost all the teachers in the country have teaching diplomas. Even though there is a high percentage of illiteracy in the coun-

ARGENTINA, EDUCATION IN

try (13.14 per cent among children and youths of school age, 19 per cent among the conscripts by the Army and Navy), and more teachers and schools are needed badly, especially in rural regions, there are more than 20,000 unemployed licensed teachers because of lack of funds to employ them. Teachers enjoy tenure as long as they retain technical ability and good conduct.

The most important medium of educational publicity in the country is the *Monitor de Educación Común* published monthly by the *Consejo Nacional de Educación*.

Secondary Education. Secondary education is carried on in public or incorporated (accredited private) institutions. The public secondary schools are under the exclusive jurisdiction of the *Ministerio de Justicia e Instrucción Pública* and, because there is no basic law (as in the case of elementary education), they are governed by decrees and resolutions of superior authorities. In matters of supervision of teaching, discipline, and administration, the Ministry is assisted by an *Inspección General de Enseñanza Secundaria, Normal y Especial*. For the control of funds there is a *Dirección de Administración*. The *Inspección General* controls directly, through a body of supervisors, all the work of the public institutes and a good part of the work of the incorporated (accredited private) institutions; apart from the function of technical orientation, it has few executive powers, acting more as an advisory board to the Ministry. In addition to the schools mentioned above, there are special schools directly controlled and administered by the Ministries of Agriculture, War, and the Navy.

The Reform of 1942, decreed by the national executive, set forth a new plan of secondary education and a new system of promotion for students. Commercial and industrial education was separated from academic education, and set up under a new plan. For the academic course a cycle of three years of basic courses was made a uniform requirement for the baccalaureate and the elementary school teacher's certificate, to be followed by two years of specialization, a total of five years (an increase of one year above the former requirement). In the basic course, the daily schedule has been made uniform; it is now five hours a day, a total of thirty hours a week; the total number of subjects has been

reduced; of foreign languages there is a choice between English and French; more time is devoted to applied mathematics.

The new system of promotions has as its principal characteristic the annual classification of the student. Examinations at the end of each course have been done away with and replaced by comprehensive examinations at the end of each of the two cycles, basic and specialization. In each subject the student is promoted if he earns a minimum of four points out of a possible ten, and shows satisfactory progress in all his subjects except a maximum of two. The judgment of the teacher prevails in this evaluation of the student's work. This new system gives greater power to the teacher and is intended to make for greater mental discipline on the part of students so that they can pass the examination at the end of each cycle. It is precisely this effect of the system that is criticized by its opponents, who oppose placing too much authority on teacher judgment and too much emphasis on mental discipline.

University Education. There are six universities: Buenos Aires, Córdoba, La Plata, Litoral, Cuyo (in Mendoza), and Tucumán. The first university was Córdoba, created in 1628 by decree of Gregory XV; the newest is that of Cuyo in the city of Mendoza. The government and control of the universities, as a result of the reform movements of 1918 and 1920, depend fundamentally upon the faculties. The faculties, meeting in common assembly, designate delegates to a *Consejo Superior* and elect the Rector for a term of four years. The *Consejos Directivos* of each faculty control educational and disciplinary matters. The *Consejo Superior*, consisting of the deans and delegates of the faculties, has jurisdiction over matters concerning the entire university. For the year 1942 the budget of the six national universities — derived partly from funds of the public treasury and customs taxes in the ratio of approximately 2:1 — totals more than 36 million pesos, as follows:

Buenos Aires	14,078,045
Córdoba	5,083,403
Litoral	6,297,744
La Plata	5,971,574
Cuyo	2,638,397
Tucumán	2,208,543
	<hr/>
	36,277,706

The universities fulfill the functions of both professional preparation and research, and scientific investigation. The faculty of Philosophy and Letters of the University of Buenos Aires has organized an institute of investigation whose publications have made notable contributions in the interest of research and public cultural action.

Relations with the United States. Cultural and educational relations with the United States have not been as close as the great opportunities for reciprocal gain seem to indicate. The distance (7,000 miles to New York); cost of traveling; and differences in race, religion, and standards of living (the American dollar is the equivalent of \$4.25 in national currency) have all contributed to this lack of intercultural exchange. However, since the 1930's, more and more efforts have been made to bring the two countries closer together. A congressional law created the *Comisión Nacional de Cultura*, which, in the period 1935-42, sent to the United States for further study 56 winners of scholarships, at a cost of \$8,000 for each one. As for the interchange of teachers and students, Argentina has not yet adhered to the Buenos Aires Agreement of 1936, in which the resolution was adopted that the countries represented (Latin American countries and the United States) should exchange students among each other. Both the Division of Cultural Relations of the United States Department of State (See CULTURAL RELATIONS, DIVISION OF) and the Argentinian diplomatic service are working to facilitate an increase of intercultural relations between the two countries.

Pertinent Statistics

Population (as of 1941):

in the 14 provinces	9,000,000
in the federal district	2,600,000
in the 10 territories	1,000,000

Total	12,600,000
-------------	------------

Number of students (as of 1941):

in elementary schools	2,024,954
in secondary schools	199,856
in universities	31,231

Total	2,256,041
-------------	-----------

ARITHMETIC MEAN—See CENTRAL TENDENCY.

ARITHMETIC, TEACHING OF. Arithmetic commonly is understood as the art of computation, and the application of this art. In the public schools arithmetic is taught, ordinarily through the eighth grade, to provide competence in performing the fundamental operations with numbers as they are required in the life of the community. Frequently, in the upper grades in particular, the concepts and processes of other branches of mathematics such as algebra and geometry enter into the applications of arithmetic. This is true when formulas are used, or when the areas and volumes of geometric figures and solids are to be calculated.

In the high school, the courses in which the processes of arithmetic, algebra, and geometry are used as needed to study the topics which make up the course are commonly designated as *general mathematics*. Some specialized fields of arithmetic have been provided in the secondary schools to develop the special competencies needed for certain vocations, as shop arithmetic and commercial arithmetic. There is a tendency to recognize here, also, that the concepts of algebra and geometry are useful, and these special courses are being referred to increasingly as *mathematics* rather than as *arithmetic*.

History of Arithmetic in America.

It is convenient to consider the development of curriculum and instruction of arithmetic as falling into three periods. The colonial period, up to 1821, has been referred to as the "ciphering-book" period, from the fact that it was characterized by a mechanical copybook method of teaching. The chief function of the teacher was to "set sums," state rules, and examine the pupil's work. Arithmetic was taught because of its practical value in business, and mainly in localities where commerce was important.

During the period of national expansion from 1821 to 1890 arithmetic rose to a place of chief importance in the schools as a result of several forces, including industrial development, a universal faith in formal discipline, and the ideas of Pestalozzi, as interpreted in the writings of Colburn. Teaching procedures, designed to provide motivation and secure understanding, received much at-

tion. Stress was laid upon development of general mental capacity.

In the period since 1890 the methods of science have been adapted to the study of education and psychology. For arithmetic, the most important results of the scientific study of education have come from the measurement movement, surveys of social usages of arithmetic, experimental research in the classroom, and child psychology and the psychology of learning. A growing fund of information from these sources is stimulating the continuing attempt to place the arithmetic curriculum and instruction on a scientific basis.

Aims of Arithmetic Instruction. The basic and dominating aim of arithmetic is to equip the pupil with understanding of the nature and use of the number system in affairs of daily life, and with ability to use quantitative procedures effectively in the achievement of his purposes and those of society. This point of view recognizes two aspects of instruction in arithmetic: the *mathematical* aspect, emphasizing the system and the logic of mathematical processes; and the *social* aspect, stressing the importance of number in modern society. Each of these aspects has, at times, been emphasized to the neglect of the other, as, for example, in discussion of the relative merits of functional and formal mathematics. It is recognized increasingly that both aspects are essential, and that arithmetic must be at the same time mathematically meaningful and socially significant.

Trends in the Curriculum. Trends in the arithmetic curriculum may be seen as the results of the shift of attention from formal discipline to the scientific study of educational problems. Of particular importance are the trends in content and grade placement.

The movement toward elimination of obsolete and useless applications and their replacement by those that are real and important has continued from the beginning of the century. Problem situations are sought in the present experiences of the pupils. In the upper grades, particularly, there is a growing tendency to organize materials around social topics rather than around mathematical processes. There is a trend toward reducing the number of topics in a given year, and toward exploring more thor-

oughly those that are studied.

In grades seven and eight there is an increasing tendency to utilize the fields of geometry and algebra in exploring the topics. The geometry is that of space and form (as contrasted with a study of the nature of proof), including: (a) the basic concepts and terminology, (b) the basic skills and techniques, such as constructions with ruler and compass, and with mechanical drawing instruments, and (c) important geometric facts and relationships that can be discovered experimentally or from observation. The methods of algebra are utilized in expressing relationships in formulas, in evaluating formulas, and in solving very simple equations.

The grade placement of topics has been influenced in an important way by the information on growth of intelligence and the rate of physical and social maturation of pupils that is made available by studies in child psychology. One result has been to establish rather definite limits in the nature of processes that can be learned economically from year to year. These are based primarily on the ability to perform the operation, to understand the situations to which it is applicable, and to deal effectively with the principles involved in the development of the operation. They affect the choice of operations to be used, and the level of reasoning involved.

The result is an interesting reversal of a general trend lasting over a century and a half. A hundred and fifty years ago arithmetic was a college subject. A hundred years ago it was specified as a college entrance requirement. The downward movement continued until only vocational arithmetic was taught in the high school, and in some schools, immediately after World War I, long division was taught in the third grade. Important social applications of arithmetic—investments, taxation, management of family income—were studied at an age when their importance and implications were not recognized by the pupil.

While the resulting reallocation of topics leaves the curriculum in a state of flux, it is clear that there is a general upward revision, and a reaction against the crowding of the entire curriculum in arithmetic into the grades. Courses in general mathematics that are largely arithmetic are being made available to an increasing proportion of high

school pupils, partly to correct mechanical deficiencies and partly to deal with important social topics.

Theories of Learning as They Affect Classroom Procedures. The nature of classroom activities is determined largely by the teacher's concept of the learning process. The point of view that appears to be most influential at the present regards learning as an active, purposeful process, rather than a passive, mechanical one. It considers understanding as more important than repetition. It considers learning as a developmental process, rather than one of fixed, stereotyped responses. It encourages discovery and problem solving, as contrasted with an insistence on an initially correct response. There is, furthermore, an emphasis on the importance of organization, by which learning is facilitated through the recognition of a form or plan. The number system provides a basis for this organization in the relationships in the number system, from which the mathematical operations are developed.

The following instructional procedures, based on this point of view as the nature of learning, are typical:

1. Considerable attention is paid to pupil interests, in order to discover those that may form the basis of significant and important uses of number.

2. Since careful research indicates that abstract ideas of number develop out of many concrete, meaningful experiences, the use of arithmetic in practical situations is increased, along with its study as a system of thought, in order to develop the pupil's ability to think quantitatively.

3. The use of out-of-class activities, laboratory situations, reference material, and other departures from a textbook activity, is increasing.

4. The fact that learning is not compartmentalized, and that along with skills and information other outcomes may be expected in attitudes, interests, and other personality traits, have called attention to the mental hygiene aspects of arithmetic. This in turn demands the use of evaluation procedures suitable for appraising growth in areas other than computational or informational.

5. The insistence of Pestalozzi that understanding precede drill is assuming a new importance. Recent statements of the desir-

able characteristics of repetitive practice include recognition of the purpose and value of the practice by the pupil, provision for self-direction and self-evaluation, and reasonable demands on attention in laying out practice schedules.

6. Diagnostic procedures are utilized to reveal to the pupil the precise nature of his weaknesses, and remedial practice and self-testing materials are provided to correct the computational and problem-solving difficulties as they are identified.

7. In so far as it is feasible in the classroom situation, increasing attention is being given to the needs of individual pupils as they demand individualized procedures and content. More effective practices are made possible through more adequate information not only as to ability to understand and use abstract mathematical principles, but also as to interests, purposes, attitudes, and other personality factors.

Recent Trends in Research. Research studies that are of particular significance have been carried out on problems of grade placement, the social uses of arithmetic, arithmetic in the activity program, and the criteria for effective drill.

It has been noted above that the upward reallocation of topics in arithmetic has indicated the need for accurate information as to the optimum level for each process and each topic. Formally organized research has been conducted in considerable detail for this purpose. The value of recognizing the factors that go to make up *readiness* for a process has been established, and the undesirable effects of mechanical learning prior to understanding have been pointed out. Studies purporting to determine "optimum mental age" for each topic or process, however, are valid only when other factors of readiness are equivalent—for example, experience, interest, and social maturity.

Related to this problem also are the studies that are concerned with the number of experiences of preschool and primary-school children. It is clear that children acquire a significant amount of number experiences before entering school. In many schools, number experiences are started in the first grade, using normal activities of children for the purpose. Some systematization of these experiences is common in the second grade.

Studies of adult uses of arithmetic played an important part in directing curricular revisions in arithmetic in the period since 1910. While providing a fund of information as to the skills and information most widely needed by adults, these studies are, of course, limited by the facts that adults use only the mathematics they have available, that these studies deal with adult needs rather than pupil needs, and that curricula must take into account *mathematical* as well as *social* aspects of mathematics.

The teaching of arithmetic in the activity program is an effort to bring pupil needs to the foreground in classroom activities. A number of studies have been carried on to determine the effectiveness of arithmetic instruction based on units of social experience. These studies are indicative of the valuable contributions that can be made by a well-organized program, provided attention is given to both the mathematical and the social aspects of the field.

Research to determine the criteria for effective drill has been one of the most popular types of research in arithmetic. The importance of many of the studies, however, is diminished by the narrowness of the outcomes measured, processes included, and techniques compared. Newer points of view with regard to optimal circumstances for effective learning have led to increased emphasis on the purpose of the learner, a factor commonly omitted from earlier research studies. Moreover, recent studies have shown an advantage for the discovery of relationships within the number system, as compared with study of the number combinations by repetitive drill. This opens up the whole question as to which areas are suitable for drill procedures, and which can be more economically studied by methods other than specific repetition of each part.

Evaluation of Outcomes. The advent of the measurement movement, which had many of its beginnings in measuring computational skills, focused attention upon the mechanical aspects of arithmetic. The influence on both curriculum and instruction had many unfortunate features which the present point of view in evaluation (*q.v.*) aims to avoid. Comprehensive evaluation requires, first, an adequate statement of outcomes desired from arithmetic instruction. From

these, the most crucial are selected for evaluation. Second, evidence is collected to determine the degree to which these outcomes are being achieved. For this purpose, there are some standard tests available for certain outcomes. Well-prepared informal tests are more commonly available. In addition, for most outcomes, evidence is needed from observation of pupils while they are engaged in their classwork and informal out-of-school activities, supplemented by reports from pupils and parents. ARMED FORCES, TRAINING FOR —See MILITARY EDUCATION.

ARRESTED DEVELOPMENT. A cessation of growth in any one area at some time during development before completion or maturity has been reached. The stoppage will result in physical deformity when occurring during fetal growth and accounts for such structural abnormalities as harelip and cleft palate. Arrested mental development may be caused by certain diseases such as encephalitis when these occur in early childhood. It should be distinguished from mental deficiency (*q.v.*), which is slowness of growth rather than stoppage of growth.

B.B.F.

ART EDUCATION. Art education aims to meet the needs for art appreciation and art production in the unified elementary school, the exploratory junior high school, the differentiated senior high school, the pro-

fessional art school, the teachers college, the college of liberal arts, and the university. Through ministering to human needs, art aims to further democratic living, thus contributing to the realization of the general objectives of education and promoting art as a way of life rather than art-as a cult.

Art is gradually achieving a place in education commensurate with that which it fills in life, largely because of the initiative and leadership of a few progressive school administrators whose philosophy of education is broad and liberal enough to include in their organizations those phases of art that contribute most to individual and social æsthetic growth, as well as those contributing mainly to mental and physical development.

The contribution made by the elementary schools to the total art education program is of paramount importance, since it is here that the educational production and appreciation of art have their beginnings, here that the greatest number of individuals are affected. Unfortunately, art is often taught in the elementary school by a classroom teacher with little or no training in art. Where the elementary schools are organized on a platoon basis, there is, if the school is large enough, a special art teacher. In smaller platoon schools, the teacher's schedule includes a combination of allied subjects. The improvement in art education that comes from having specially trained art teachers in the elementary schools is obvious.

Art instruction in the junior high schools, carried on by a trained art teacher, is exploration and guidance, with emphasis on art appreciation. In the senior high schools, where art is usually an elective subject, special training is provided for those pupils who can profit most from the instruction given. When art is offered in the secondary schools as a major subject in a special curriculum, the subject is intended to represent in a general way the entire art field. In the art curriculum offered in some large senior high schools, provision is made for considerable specialization in a single art field. This curriculum, a four-year sequence of studies with art as the subject of major interest, is planned for boys and girls whose ultimate objective is such an occupation as painter, sculptor, architect, illustrator, occupational therapist, art teacher.

The typical special art curriculum presents

a balanced offering of art experiences. The art courses included are General Art, Painting, Commercial Art, Sculpture, Industrial Art, Theater Art, and Architecture. Although the art subjects must be taken by all who enroll, the students are allowed, in so far as possible, to elect those academic and related subjects that will help them gain admittance to the institutions of higher education they hope to attend. Interested and able students who desire to make art their life work are encouraged to follow the art curriculum. The art curriculum graduate is eligible for both college and art school.

The liberal arts college further familiarizes its students with the art heritage of the race in its relation to the present, enabling them to utilize the æsthetic resources the environment affords. Some liberal arts colleges offer studio or activities courses. Most special art schools make some provision for training art teachers.

Little formal instruction in art should be found necessary at any level of the child's progress through school, although there is an appropriate place for the teacher's skillful guidance, given always at a time in the pupil's development when the help is needed. To facilitate the learning process, experience in school is often divided into parts convenient for assimilation by the pupils. Such a part is generally referred to as a "unit of experience," although "unit of teaching" and "unit of work" are terms also used to refer to the same idea. The teaching unit in art embraces experiences with information and experiences with activity, the information being both general and technical in order to assure a broad cultural background. The activity included is both directed and creative to assure consistent pupil growth in the manipulative phase of the subject.

The following sequential steps are distinguishable in well-planned units of experience in art: (1) orientation, (2) design, (3) forming products, and (4) appreciation. *Orientation* signifies finding one's bearings and getting set for the work anticipated. *Design* implies conceiving and planning, regardless of whether or not a drawing or model is to be made in advance of the actual construction of a product. Design includes decoration. *Forming products* involves the transformation of materials into art form, thus accomplishing

ART EDUCATION

the purposes of design. *Appreciation* involves judgment of the educational results, as well as evaluation of the art products made by the members of the class.

In all his work, the pupil should be allowed to choose the materials that seem to him best fitted to embody his own ideas. If teaching has been effective, there is little danger that the pupil himself will not possess æsthetic judgment sufficient to meet his art needs at any stage of his growth.

Art appreciation refers to the entire process of responding æsthetically to art. Implying sensitive awareness to æsthetic values as well as ability to evaluate art products, art appreciation is both emotional and intellectual. Quality in works of art is determined largely by the design that enters into their formation, as well as by the materials used and the technical processes involved. People differ in their opinion of what is appropriate in design, materials, and processes, and this difference of opinion gives rise to taste. Assuming that one's taste may be improved, art education aims to develop art appreciation in boys and girls by providing experiences that make possible the exercise of discriminative judgment. These experiences need not be isolated art experiences but may be closely associated with other school and life activities.

Although it may, and often does, result from creative experience, art appreciation is not merely for the child with unusual creative ability, but should be nurtured in all; good taste and the preservation of acceptable ideals of beauty are matters of not only individual but also community concern. Appreciation cannot be taught but must be cultivated through continuing contact with an art environment. To appreciate an art fully the child should be acquainted with it both emotionally and intellectually and should be brought to understand its significance in civilization. He should be made acquainted with its evolution (history) and with its masters. He should be enabled to interpret its products by means of sense perception; to differentiate between qualities — distinguishing between poorer and finer grades and making defensible choices; ultimately to employ this power in the selection of products, in their use, and in their combination and arrangement.

The need for adequate direction of art education is urgent, particularly in the elemen-

tary schools where teacher preparation in art is generally in inverse ratio to the demand for art. In any community, large or small, art education is a cooperative enterprise in which the supervisor, the principal, and the teacher should share. It is important that all these educators should have an adequate conception of art as a curriculum area, and of the school procedures applying to art; that all should recognize the validity of the claim of art to adequate time and emphasis in the weekly and daily schedules; and that all should realize that art supervision, whether employed by an art director or supervisor or by a school principal, must concern itself with all these things.

In the small community a single individual may have to teach art and, in addition, do such supervision as time will permit. In the large community, responsibility for administering art education is centered in a director or a supervisor working under the superintendent of schools and his assistants. There is, of course, a wide variety of possibilities between these two extremes.

The criteria for judging the effectiveness of the art education program in a particular educational organization include the following: interest of the head of the institution in promoting art, adequacy of the philosophy underlying the art program, provision for special needs, integration of art and other curriculum area, diversity of integration or the number of curriculum areas involved, educational value of the activities undertaken by the pupils, character and quantity of information experience provided, variety and educational possibilities of the mediums used, balance between two- and three-dimensional art products, evaluation of pupils' work, adequacy of rooms and equipment, and maintenance of rooms and equipment. (See ART SCHOOL.)

ART METAL WORK. Professional artists would normally restrict the word "art" to production of superior quality and of original design. Although much of the art metal work done in the schools is not of original design, the emphasis in the better schools is in the direction of fostering original design.

The instruction centers about metal work that has æsthetic as well as utilitarian value. Most instruction in art metal work, as given by secondary schools, is general or cultural in aim. In some schools it is administered by the industrial arts or by the practical arts department. In other schools it is administered as a phase of art education. In others, the instruction is definitely vocational and meets the requirements of the State Plan for Vocational Education. Such metals as copper, brass, aluminum, pewter, stainless steel, and silver are used when available. Iron and steel are also employed.

F.T.S.

ART SCHOOL. The art school is a separately organized educational institution whose purposes generally include (1) the training of artists, (2) the education of consumers of art products, and (3) the preparation of art teachers. The purpose of the art school is to teach the use of art media including the tools and materials of expression, and thus to meet the social, democratic, and practical industrial needs of the modern community. Some typical examples are Pratt Institute, School of Fine and Applied Arts, Brooklyn, N. Y.; Rhode Island School of Design, Providence, R. I.; The Maryland Institute, School of Fine and Practical Arts, Baltimore, Md.; and The Cleveland School of Art, Cleveland, Ohio.

Graduation from a four-year high school is generally required for entrance to the art school, the curriculum of which is usually four years in length. This curriculum gen-

erally places emphasis on one or more of the following fields: the assembling arts, such as display; architecture, exterior, interior and landscape; costume; the graphic arts, such as advertising, illustration, photography and print-making; the handicrafts, such as ceramics, metal working, textiles, paper and wood-working; industrial design; painting, sculpture; and miscellaneous fields, such as lecturing, library work, museum work, teaching and writing.

The art school curriculum includes a general foundation course followed by specialized courses in one or more of the branches enumerated. The foundation course of one or two years' duration includes experience in drawing, design, lettering, color, English, history, and science, and sometimes in other subjects, both studio and academic. Special courses include concentrated work in such fields as painting, sculpture, architecture, graphic arts, textiles and clothing, jewelry and silversmithing, interior design, industrial design, glass and ceramics, illustration, photography, arts of the theater and other important divisions of visual art, and art education. Degrees are often conferred on the graduates in accordance with accepted academic standards. A number of art schools now make it possible for qualified students to continue their training on the graduate level for a period of one or two years. (See ART EDUCATION.)

ARTICULATION. Articulation in the educational program is secured when all aspects of the program contribute with maximum effectiveness to the continuous and cumulative growth and development of pupils in desirable directions. Poor articulation is indicated by undesirable repetition, duplication, or omission of subject matter or learning experiences in the total educational program for any one child; by sharp breaks, arrests, or gaps in the child's progression through school; by artificial or unnecessary administrative distinctions among units in the school

ARTICULATION

organization; or by the subjection of pupils to sudden and abrupt changes in curriculum organization, teaching methods, or methods of work.

The problem of articulation is most pronounced in relation to the unification of the curriculum of the various administrative units of the educational system, such as the elementary school, the junior high school, the senior high school, the college, and the university. This is due in part to the separateness of each of these school units in its historical antecedents, with the result that full coordination of purpose and function has not been achieved, and in part to organizational cleavages fostered by administrative practices relating to the salary, training, and assignment of teachers, and to the budget, control, and recognition of the school.

Good articulation results primarily from general agreement of all teachers and administrators in each administrative unit on the fundamental purposes and aims of all education and from an understanding by the staff of each unit of the ways in which it may best contribute to the growth and development of its pupils in line with these basic purposes. It is the desirable growth and development of pupils which provide the unity for the planning of educational experiences, and hence the means by which good articulation is achieved. Each administrative unit should be differentiated in curriculum, instructional procedures, and administrative practices only in terms of the needs and interests of the pupils at the level of maturation encompassed within its student body.

Many administrative measures for securing better articulation have been advocated and practiced. Chief of these is the formulation through cooperative group action of a statement of a basic philosophy of education to which teachers in all schools and at all levels subscribe. Articulation is also facilitated by the elimination of sharp breaks or interruptions in the pupil's progression. Formal graduation exercises and diplomas, as well as formal admission procedures and entrance requirements, are deterrents to good articulation.

One of the aims of the junior high school and the junior college has been to bridge the gap between elementary and secondary and between secondary and higher education. This

aim has been implemented in these institutions by exploratory courses, gradual introduction of new subject matter, and emphasis on individual guidance. However, it is doubted by some educators whether the junior high school and the junior college can achieve this aim. It is pointed out that where there were once but two gaps (between the elementary school and the high school and between the high school and college) there are now four (elementary school-junior high school, junior high school-senior high school, senior high school-junior college, and junior college-college). Moreover, it may be unwise to consider the transition function of these schools as of dominant importance since for so many students these schools do not represent a transition to higher levels, but the termination of schooling.

The use of cumulative records which assemble adequate information about the scholastic, social, and personal characteristics of the pupil, including his test results and health reports, and the transference of these records to each new unit along with the pupil, aid in providing for a continuity of experience, and hence facilitate good articulation. Joint curriculum committees composed of representatives of all educational levels, joint research projects, longitudinal studies of pupils' needs and interests, experiments, surveys, and discussions and conferences involving educators from all levels also promote articulation. A coordinated guidance program is a major factor in promoting articulation.

Within the individual schools themselves articulation is facilitated in general by administrative practices that enable a teacher to work with a given group of pupils a maximum amount of time. Hence in the elementary school good articulation is hindered by extensive departmentalization, quarterly and semi-annual promotions, artificial grouping methods, and the assignment of teachers to work with groups for only a year or a semester.

In the secondary school, extreme emphasis on specialization and on the mastery of logically organized subject matter to the neglect of wholesome, all-round development of youth hinders articulation. Other practices in the secondary school which may be detrimental to good articulation are the use of a rigid unit system of credits, rigid graduation re-

quirements, ability grouping, and the distinctions between academic and the various practical or vocational subjects with respect to credit, acceptability for graduation, and uniform time schedules. G.S.

ARTS AND CRAFTS—See CRAFTS.

ASOCIAL. An *asocial* individual is one who violates the accepted social standards of the home, school and community. The term does not apply generally to confirmed criminals, but rather to delinquents who may come either from impoverished, broken, or otherwise undesirable homes or from financially solvent families.

Every individual has some asocial tendencies but whether or not they become serious depends upon the frequency and persistence of their occurrence, the importance which the person attaches to his conduct, and the type of guidance he receives.

In treating children with asocial tendencies, every effort should be made to ascertain the underlying causes for the behavior, and then to develop appropriate corrective measures. These may include the re-education and adjustment of the child and his family, or his removal from the home or community. In these problems prevention is a most important feature, and parents and teachers should help the child who feels defiant and sullen to regain his self-confidence and self-respect. (See CHILD GUIDANCE CLINIC, EXCEPTIONAL CHILD, JUVENILE DELINQUENTS, LYING, MENTAL HYGIENE, NEGATIVISM, REJECTED CHILD, STEALING, TRUANCY, VANDALISM, and similar items.) R.V.M.

ASSEMBLY, SCHOOL. The school assembly is a development of the early college and high school chapel—a purely religious service that dates from the time when the college prepared its students almost entirely

for the ministry. With the growth of public and nondenominational education, the assembly lost its predominantly religious character. As educators began to recognize its educational possibilities, the assembly changed emphasis and developed from merely a formal ceremony to one of the most vital and important of all school activities.

The assembly is usually scheduled regularly once a week and at such other times as occasion demands. Its main purposes may be listed as follows: (1) to unify the school, (2) to educate in the common and integrating knowledges, (3) to motivate and enrich classroom work, (4) to broaden and deepen student interests, (5) to inspire worthy use of leisure, (6) to develop the students' æsthetic sense, (7) to instill the commonly desired ideals and virtues, (8) to develop self-expression, (9) to emphasize correct audience habits, (10) to publicly recognize worthwhile achievements, (11) to promote intelligent patriotism, and (12) to correlate school and community interests and achievements.

In order to be most effective, the assembly program should (a) have both educational and inspirational merit, (b) have interesting variety, (c) represent the work of all the school—both curricular and extracurricular, (d) provide for teacher and student participation, (e) stress education of the audience rather than training of the performers, (f) represent worthy standards in materials and presentation, (g) utilize demonstration, exhibition, and dramatization as much as possible, (h) include relatively few outsiders, (i) be closely supervised by competent teachers and committees, and (j) be held in regularly scheduled school periods.

If the assembly is to achieve optimum results it must be carefully planned and supervised. This means that a single individual, or, better still, a committee of teachers or of teachers and students, should be assigned full responsibility. This individual or group educates the school in the purpose of the assembly, surveys the school for suitable material, assigns available dates to a particular group or individual, assists in staging, equipping, and advertising the program, develops standards, keeps scrapbooks or files of programs and program materials, and organizes and promotes interschool pro-

ASSIGNMENTS

gram exchanges. Each of these responsibilities may be assigned to subcommittees.

Good assembly programs should be built on material that is vital and suitable for the group and should be as natural as possible both in material and in presentation. They should possess pleasing variety, offer some opportunity for audience participation, and include a considerable amount of good music.

A great number of devices are now utilized in order to achieve these program objectives—talks, conversations, interviews, demonstrations, exhibits and explanations, dramatizations, debates, competitions, questions for the audience (voting, oral true and false tests, expressions of preference, "What would you do?" questions, etc.), slides, motion pictures, and radio.

ASSIGNMENTS. While the term *assignment* is ordinarily used to refer to tasks which the pupils are asked to do outside of class, the best present day interpretation refers to the assignment as a definitely designated activity or set of activities to attain certain learning outcomes that contribute to the development of the classwork, whatever that may be. Thus, while assignments may well consist of such activities as working exercises to develop certain abilities, studying assigned topics to get understandings, or writing stories to develop creative abilities, they may equally well consist of any valuable learning activities that pupils need to engage in independently to attain desired ends. In our public schools it is common practice to make assignments to be done during a part of the class period, often designated the study period, or to make assignments which the pupils are expected to work on at some time before the class meets the next day.

Besides the primary purpose of bringing about certain desired learning activities, the

assignment should fulfill other important purposes. It should (1) provide a stimulating approach to the new work and show its purpose and relation to what is being done in class, (2) establish a motive for engaging in the activity, (3) provide for individual needs and interests, and (4) provide study helps or directions so that the activities can be carried out effectively and economically.

To realize these purposes teachers must plan carefully and use effective techniques. Many teachers make effective use of an introduction or so-called approach before giving the assignment proper. By means of this introduction the teacher sets up objectives, motivates, and orients the pupils. Then the assignment of learning activities for the attainment of the objectives is made, with appropriate provisions for individual needs and interests and needed helps or directions for work.

Several other factors have a bearing upon the effectiveness of assignments. The amount of time and the appropriateness of the time are important. Many assignments are poor because the teacher does not take enough time to fulfill the purposes of an assignment. Also, the assignment should be adapted to the abilities of the learners and to the attainment of the kinds of outcome desired. Some teachers make effective use of the cooperative assignment in which pupils and teachers cooperatively decide what should be done.

For purposes of comparison it is advantageous to classify assignments according to types; for example, creative, practice, remedial, etc. However, no single classification is satisfactory, since their merits must be compared on different bases. On the time basis the daily assignment is the one most commonly used. Such an assignment covers the work for one class period and is usually made by the teacher each day as the work progresses. This type of assignment allows for the adaptation of the work to the needs and progress of the class. Its greatest weakness is the danger of failure on the part of the teacher to unify the work. Because of this weakness, longer-span planning is gaining in favor, and more emphasis is being put upon "long-span" or "unit-assignments." Such assignments are designed to unify the work, thus helping pupils to see their daily work as a part of important phases or aspects of each

course. The term *unit assignment* has been suggested as a term to apply to all long-span assignments, whatever the basis of planning, including such types as the contract plan, the differentiated unit assignment, the project, and the Morrison unit plan. All such long-span assignments, however, need more or less day by day adaptations or supplementary assignments. Ordinarily assignments are group assignments for the class as a whole, but special assignments are given to individual pupils to provide for special needs or interests.

The *differentiated* or *flexible assignment* is a special type of long-span or unit assignment made up of learning exercises of different degrees of difficulty organized usually on different levels corresponding to the grading system used by the school. Such assignments are designed to provide for individual differences in abilities and in interests and to allow pupils to progress according to their abilities. When pupils are encouraged to share their experiences with the rest of the class, the use of differentiated assignments may give the entire class a richer background for discussion than is available when the same assignment has been done by all the students. The use of differentiated assignments does add to the demands on the teacher's time both in the selection and adaptation of assignments to meet the needs of individual students and in the additional time required for evaluating pupil performance on a variety of tasks.

The following criteria have been suggested for the evaluation of assignments:

1. Are the objectives attainable and appropriate to the particular learning situation?
2. Are the learning exercises adapted to the attainment of the objectives?
3. Are the objectives and learning exercises clearly understood by the pupils?
4. Is the assignment adapted to the abilities of the group?
5. Is the length of the assignment adapted to the time available for preparation?
6. Are the past experiences of the pupils made use of in making the assignment?
7. Are desirable means of motivation used in stimulating pupils to engage in the assigned activities?
8. Are adequate references given so as to conserve time and help pupils get at the most important data needed?

9. Are adequate directions for study made so as to assure effective procedures in studying?

10. Is the assignment adapted to individual needs as far as possible under the circumstances?

11. Is the assignment made at a time best adapted to the learning situation and the nature of the assignment?

12. Is the time used in giving the assignment well adapted to the nature of the assignment and the ends sought?

The assignment occupies a more important position in the teaching-learning process than it was accorded a generation ago. At that time it would have seemed odd that anyone should recommend that the assignment be allotted from a fourth to a third of the time spent in a typical high school class. Part of the increased prestige of the assignment arises from the greater emphasis on pupil activity and from the value of the assignment as a means of guiding this activity. Another factor which has made the assignment an important part of the typical class session is the recognition that the assignment is a useful means of improving the students' study habits and their ability to work with a minimum of direct teacher supervision. As the assignment became a recognized part of the lesson rather than a brief enumeration of chores to be done, teachers saw in it a procedure for enriching the scope of the curriculum and for adjusting the curriculum to individual differences in interests and abilities. Despite the attention that is given in some classes to the planning of the assignment, it is nevertheless true that in all too many classes the assignment is still dismissed briefly with a mere announcement by the teacher of the pages to be read, the questions to be answered, and the problems to be solved. ASSIMILATION

ASSIMILATION. In general psychology, assimilation refers to the process of receiving new facts or responding to new stimuli in conformity with what has been previously experienced. It describes a phase of perception by which new experiences are so modified in the mind as to take on the character of previous experiences, even though the form of the new may be somewhat different from the old.

In modern educational psychology, the principle of assimilation is recognized as a fundamental principle of learning. Stated in simple terms, it means that learning must proceed from the known to the unknown, that all new knowledge must be interpreted in terms of past experience, that nothing can be learned that cannot be understood and mastered. *Pestalozzi* (*q.v.*) protested vehemently against teaching generalized ideas to the pupil in the form of meaningless words, the "teaching of the unknown by means of the incomprehensible". *Herbart* (*q.v.*) took *Pestalozzi's* principle that learning must proceed from the known to the unknown and elaborated it into the doctrine that new knowledge always is assimilated in terms of what the learner already knows. Assimilation, according to *Herbart*, occurs only when the pupil is interested in the new experience, and to be interested the pupil must have something in his mind which will cause him to attend. In order to assimilate, the pupil must be in the proper frame of mind to attend, and must also have a stock of related ideas which will enable him to interpret correctly and respond adequately to the new situation. *Herbart* insisted that only large, connected units of subject matter are able to arouse and keep alive the deep interest of the pupil's mind, and thus bring about complete assimilation of the material.

Herbart's doctrines paved the way for what has been called the most widely accepted innovation in teaching of the last twenty years in American education, the "unit mastery" plan, proposed and popularized by *Henry C. Morrison*. Dissatisfied with the desultory "lesson-learning and recitation" methods of the secondary schools of his day, *Morrison* developed his mastery technique. Instead of the assignment of a few pages of the textbook to be assigned one day and recited upon the next, he advocated the organization of subject

matter into units, and varied the techniques used through several distinct steps, the most important of which was the step of assimilation. His steps were a variation of *Herbart's* five formal steps, and were spread over several days or weeks instead of over a single class period. These steps are (1) *exploration*, consisting of a pretest, a quiz, or an informal discussion, to ascertain the apperceptive mass of related material, to arrive at a suitable starting point for study, to avoid repetition and waste of time and effort; (2) *presentation*, consisting of a short preview or overview by the teacher, to present a "road map" of the territory to be covered, to arouse interest and to establish goals; (3) *assimilation*, consisting of supervised study and discussion, based upon guide sheets or assimilation charts, accompanied by "mastery tests" to check on the extent of assimilation or mastery; (4) *organization*, consisting of the construction of student outlines of the unit, without recourse to notes; (5) *recitation*, consisting of a series of student floor talks to exhibit actual and complete assimilation and mastery of the unit. Most of the more recent textbooks are organized on this concept of assimilation through unit teaching, and the *Morrison* technique has been exceedingly valuable in correcting many of the weaknesses of the old-fashioned recitation methods.

Some educators have objected to the emphasis which has been attached to assimilation in teaching. Their objection does not deny that we learn new material only in terms of what we already know, but it does emphasize the dynamic quality of education today with its emphasis upon the child's needs and interests. Critics see in the stress on assimilation a reminder of the point of view which regarded the child as the passive recipient of teaching. If a new concept has to be taught to children, then the teacher is forced to find something in the child's background to which the new concept can be related. On the other hand, if the child's activities are the beginning point of education and if he learns in order to satisfy a felt need, the assimilative background for the new learning is already there. Thus if the elementary school teacher has to teach the concept of discount in arithmetic simply because that is the next item in the syllabus for the term, his is the very real problem of finding ways of facilitating assimilation. If, however, the children want to know about dis-

counts because they are putting on a play and are comparing the cost of costume materials when bought at department stores with the cost of purchasing from concerns that offer a special discount to schools, the need for understanding is so real that assimilation is not likely to present much of a problem. ASSISTANT TEACHER. The term *assistant teacher* is used in some school systems to designate a beginning teacher or one with relatively little experience, who is assigned to a more experienced and competent teacher in charge of a grade or class. The assistant teacher may be thought of as a helping teacher or as one who carries on certain functions in the classroom. Often the assistant teacher is one who is in training and who is under an extended period of directed teaching under the supervision of the regular teacher in a teacher education institution. (See STUDENT TEACHING.) The term should not be confused with the office assistants or clerks for teachers, whose duties are entirely clerical.

The term assistant teacher is seldom used in the literature and any clear designation of the duties of such a person is difficult because of the local character of the assignments. When the assistant teacher is a qualified person assigned to an experienced teacher, his duties consist of various phases of classroom work,—working with individual pupils, guidance, conferences, playground supervision, etc. W.C.R.

ASSOCIATE LEARNING—See LEARNINGS, SIMULTANEOUS.

ASSOCIATION. The process of *association* is the connecting of ideas or other aspects of behavior in such a way that one may be aroused by the other, and that action appropriate to an absent stimulus is called forth by a present stimulus with which it has been associated in some way in the past. One theory of association can be traced back to Aristotle, who formulated four causes or laws of association: (1) sequence in time, (2) closeness in space, (3) similarity, (4)

contrast. It often has been assumed that these "causes" explained "association" and that the term "association" explained the learning process. Behaviorism (See PSYCHOLOGY, SCHOOLS OF) makes the principle of "contiguity" (closeness in time and space), using Aristotle's first two "laws," the basis for its explanation of learning by "conditioning." The Behaviorists have discarded "similarity" and "contrast" as *subjective* explanations that depend upon the "mental activities" of the learner, while retaining "sequence in time" and "closeness in space," which they regard as *objective* factors having scientific validity.

With the development of physiological psychology, association has often been explained in terms of neurones which would almost automatically set each other off, because, in the past, the stimulus which went along one neurone was repeatedly followed by a response which was conducted along another neurone. A sort of brain pathway bond is said to be established between any two brain centers that are active at the same time. Thus laws of association now become physiological laws instead of laws relating to mental states. Behaviorists and "Connectionists" accept a neural explanation of this type. Gestalt psychologists do not (See PSYCHOLOGY, SCHOOLS OF), neither does Dewey (*q.v.*) who, in addition, discards all four of the Aristotelian principles as explanations. He points out that qualitative thinking determines which associations will be made in situations where learning is occurring: "association is a name for a connection of objects or their elements in the total situation having a qualitative unity"; "thinking is association as far as the latter is controlled." That things become associated because of a relation existing between them, and the fact that learning proceeds through the discovery of relationships rather than through the acquisition of the arbitrary and random associations occurring in time and space is a belief held by Gestalt psychologists as well as by Dewey and other pragmatists. They also point out that a stimulus present now does not necessarily reproduce (in the form of recall or action) the item associated with it in the past. Instead, what is recalled is a function of present purposes. These controversies over the character of "association" constitute warnings against accepting "association" as an explana-

tion of education without further inquiry into the particular kind of "association" cited.

Different teaching procedures follow from the various theories of association and of the relation of association to learning. On the one hand we have the emphasis on getting the learner repeatedly to make a certain response to a certain stimulus if we wish that stimulus finally to call forth that response without prompting on our part, and the stress on getting the learner to repeat together phrases that we wish him to remember together, for example, events and dates, two numbers and their product, etc. From the other point of view, the emphasis is placed upon giving the learner material which is organized and helping him to discover the organization and the relations existing between the various parts, or on letting him confront a problem where he must make such connections between things that will produce a solution.

Association tests. Association has been made the basis for a variety of testing devices. A stimulus word (written or oral) is given and the subject is asked to respond to it in words. Association tests fall into two categories: *Free Association* tests and *Controlled Association* tests. In free association tests used largely in psychoanalysis, the subject is started on some response and is asked to put into words any thoughts that continue to come to mind. No time limit is fixed and the psychoanalyst may, if necessary, prompt or encourage the patient to continue. After one or more such periods, the content of the subject's free associations is analyzed and interpreted as a basis for personality diagnosis. In several tests the stimulus which is used to call forth continuous free association is pictorial. Murray's *Thematic Apperception* test uses pictures portraying some incident, while the Rorschach test (*q.v.*) uses a set of meaningless inkblots, some black and white, some colored. A second method of continuous association is to give the subject a stimulus word and to ask him to speak or write as many words (not phrases or sentences) as occur to him within a fixed time. The Binet Scale includes such a test. Here the number of words given are counted. It is found that the number of words increases with age and that norms (*q.v.*) can be established. The series of words given may also be analyzed for content and sequence. This

is done in personality testing.

In a third method of free association, called "free discrete association," the examiner gives the subject a series of words to each of which the person is asked to respond with the first word that comes to his mind. In this single-word response method the time elapsing between each stimulus word and the giving of the response is often measured. Words which show a variation from the average time which the subject takes to reply are analyzed. Words that the examiner believes may be significant in relation to the person's emotional difficulties may be inserted in these lists and particular attention paid to the responses given, as well as to the time taken. Records may also be made of the psychogalvanic response reaction which occurs together with the hearing of the stimulus word and the giving of the response. Such techniques are used by psychiatrists to uncover some complex which they believe the patient may have and they have also been used as a "lie-detector."

There are several single word free association tests that have been standardized. One of the best known is the Kent-Rosanoff Single Word Response List. For standardization, the test was given to thousands of persons and the frequencies of the various responses given to each word were listed. The high frequency words are designated as *common* responses, the low frequency words as *atypical* or *individual* responses. Kent and Rosanoff found that normal persons, on the average, gave a larger proportion of common responses than did the insane. The overlap, however, is so great that these idiosyncrasy scores cannot be used to diagnose insanity.

Controlled association tests limit the subject's response in one of two ways. For the measurement of intellectual ability, the type of association to be made is specified. He may for instance be asked to give the opposite of such words as: *yes, summer, white, above*. Other relationships such as part-whole, genus-species, etc., may be called for. Scoring is done in terms of the correctness of the response.

The controlled association tests used for personality measurement present the subject with the stimulus word and the alternatives from which he must select his association. The significance of the selection is determined on the basis of similarity of response as com-

pared with the majority of certain criterion groups on whom the test has been standardized and who represent normal individuals, and also individuals who are atypical with respect to the personality trait which is being measured, or who represent groups having different interests, or who have traits at opposite ends of a polar scale. Such tests have been devised for the measurement of interests, of masculinity-femininity, of sanity, courtesy, honesty, etc. Some are considered to be much more valid than others but the majority are sufficiently doubtful to be of little practical use.

ATHLETICS. The term *athletics* is used to denote exercises, games, and sports requiring endurance, strength, skill, and agility. School and college athletics fall into two distinct categories: intramural, and interschool or intercollegiate. *Intramural* athletics, as the name implies, are confined to competition between teams made up within the individual school or college. *Interscholastic* or *intercollegiate* athletics include competition between schools or colleges by representative teams.

In general the athletic program in elementary schools and junior high schools is confined to the intramural phase. Such a program offers the benefits of competition without the attendant evils that often result when school championships are at stake. Senior high schools, colleges, and universities promote both an intramural and an interschool program. Most institutions, whether they be high schools or colleges, now seek

to maintain a sane balance between the two. American tradition has long upheld interscholastic and intercollegiate athletics. Educators have succeeded in removing much of the stigma once attached to them by wise enforcement of eligibility rules and by eliminating many of the vicious practices that once existed. The extension of the intramural program, offering as it does opportunities to the entire student body to participate, has done much to allay the criticism that interscholastic and intercollegiate athletics were only for the chosen few. Strangely enough, one of the evils of intercollegiate athletics consistently pointed out in the past—that of big business and commercialism—has resulted in the development of huge intramural activities buildings and extensive athletic fields for the promotion of athletics for the entire student body.

This extension of facilities has worked for the benefit of girls as well as boys. Athletics for girls is now accepted universally as a valuable intramural activity. Girls indulge in very little interschool or intercollegiate competition and where such competition does exist it is confined largely to the informal type in which the social values are emphasized equally with the physical. In general girls' athletics has been more progressive in realizing these values and other educational implications than has boys'. This is doubtless due to the fact that boys' athletics, because of its popular appeal and newspaper publicity, has been subject to greater outside pressure without an offsetting control by school authorities. Communities were so frequently intent on a winning school team that the coach, knowing that his livelihood depended on winning a certain percentage of games, had little time for anything but emphasis on championships. As this pressure has been relieved and as coaches have assumed the positions of teachers and professors of health and physical education, the educational implications of the program have been given more consideration.

The values of a well-balanced program of intramural and interscholastic athletics are both biologic and social. If the program is wisely administered, participants should improve in organic vigor, neuro-muscular skill, and general health. They should learn to think quickly and to act with judgment and

decision. They should develop those attributes that are synonymous with good sportsmanship such as courtesy, self-control, and fair play. To be sure, the extent to which the improvement in these traits and abilities will transfer to other phases of the student's life and become lasting personality characteristics depends on many factors, many of them beyond the school's control.

On the other hand, if too much emphasis is placed on championships, proselyting is encouraged, payment of athletes is condoned, eligibility rules are ignored, professional coaches are hired, and the physical welfare of those not able to make the varsity team is disregarded. Under these conditions athletics has no place in an educational institution. It assumes professional characteristics and had better be left in the hands of professional promoters. Schools and colleges which weigh the values and evils inherent in athletics and evaluate their programs in terms of educational worth have little difficulty in organizing these on a sound basis. ATTAINMENT AGE—See EDUCATIONAL AGE.

ATTENDANCE OF PUPILS. The term attendance as used in education refers to the presence of pupils in school. The terminology of child accounting has undergone many changes since the National Education Association began work on the problem in 1871. Although it is not yet uniform in the various states, sufficient uniformity has been attained to provide a basis for comparison and for securing national statistics on pupil attendance.

Membership. A child is a member of the school from the time he enters until he is transferred to another school, removed by death, or withdrawn from school for any reason. Membership is usually computed as total registration plus transfers minus withdrawals.

A day of attendance. A day of attendance is variously defined as the child's presence in school for any part of the day to a full day's attendance. Counting attendance by

half days is fairly common practice, in which case a half-day's attendance requires the pupil to be present in school for one-half or more of one of two daily sessions.

Aggregate days attended. The aggregate days attended is an important school statistic because it is the basis upon which other data are computed. It is obtained by counting the number of days each pupil attended school and then adding these numbers.

Per cent of attendance. The per cent of attendance is the aggregate days attended divided by the aggregate days enrolled. The aggregate days enrolled is the number of days of possible school attendance from the time a pupil's name is entered on the roll until it is officially withdrawn.

Average daily attendance. The average daily attendance is the aggregate days attended by all pupils divided by the number of days of school. This term is losing some of its importance as the terms *aggregate attendance* and *aggregate enrollment* are becoming more accepted.

Attendance worker. The enforcement of compulsory attendance laws is the responsibility of various attendance officers. The older type of attendance officer was usually a sheriff, one of his deputies, or some other police officer. His chief qualification was a knowledge of the law, and he regarded his duty as one of law enforcement. The older type of attendance worker has now largely given way to a newer type who is a trained social case worker, a school psychologist or psychiatrist, a school nurse, or a school counsellor. His qualifications are such as to fit him to deal with the social problems which are inherent in non-attendance. It is distinctly work in guidance and counselling rather than in law enforcement. (See JUVENILE DELINQUENTS; SOCIAL SERVICE ACTIVITIES IN SCHOOLS.)

Amount of attendance: Since 1870 the increase of school enrollment has been more rapid than the growth in population. This is in part due to the enrollment of an increased proportion of the children of school age. The proportion of children enrolled who were in daily attendance has increased from 59.3 per cent in 1870 to 85.8 per cent in 1938. Table I shows the total population, the school enrollment, and school attendance, by decades from 1870 to 1938.

TABLE I
Population, Enrollment, and Attendance, 1870-1938
(In thousands)

Year	Total Population	Pupils Enrolled	Average Daily Attendance	Per Cent Attending per day
1870	38,588	6,871	4,077	59.3
1880	50,155	9,867	6,144	62.3
1890	62,622	12,722	8,153	64.1
1900	75,602	15,503	10,632	68.6
1910	91,972	17,813	12,827	72.1
1920	105,710	21,578	16,150	74.8
1930	122,775	25,678	21,264	82.8
1938	130,215	26,975	22,298	85.8

ATTENDANCE OFFICER—See COMPULSORY ATTENDANCE; SOCIAL SERVICE ACTIVITIES IN SCHOOLS; TRUANCY.

ATTENTION. As popularly used, *attention* often connotes a supposed mental faculty or power by which one's field of experience can be restricted "at will." Thus, we speak of "directing," "paying," or "concentrating" attention. For experimental psychologists, however, the term refers not to a faculty or power, but to a descriptive aspect of either consciousness or behavior.

Earlier writers on attention regarded consciousness as the chief object of psychological study, and accordingly they commonly defined attention in subjective terms. Two such definitions have been frequent: (1) For structuralists (e.g., Titchener and his school), attention refers to the fact that the contents of any state of consciousness are experienced with at least two, and possibly more, different degrees of attributive clearness or vividness, often called "attensity." In attention, certain items of consciousness (those attended to—e.g., the words perused at the moment) stand out most clearly as focus or foreground, while other items (e.g., surrounding printed

matter) are less vividly experienced as margin or background. For structuralists, attention is simply this patterning of consciousness arising essentially from one or more differences in the clearness of its central and peripheral contents. (2) For functionalists, however, (Angell and others) analysis of the structure of consciousness is secondary to a study of the role of mental processes in the organism's adaptation to its environment. Accordingly, these writers frequently use the term attention to refer not to the arrangement of conscious content, but to the conscious process of selecting,—the process of focusing certain features of an experience so that they become clearer and more vivid. (See **PSYCHOLOGY, SCHOOLS OF**.)

In contemporary discussions of attention, the older definitions in terms of introspective experience are still often used. On the other hand, many psychologists have come to prefer a behavioristic definition of this as well as of other psychological concepts. From this latter approach, attention is a collective term for the behavioral processes that facilitate an individual's response to a given stimulus or stimuli (the "objects" of attention) and simultaneously inhibit his response to other stimuli. In other words, attending is used as a name for the adjustments (sometimes collectively termed "set" or "posture") giving behavior its selective and focalized character in a given situation. Although the physiological bases of these processes are yet to be fully described, the adjustments in question are often overtly observable even in everyday experience. Prominent among them are motor adjustments of the sense organs (e.g., an attentive batter's fixation and visual pursuit of the oncoming ball), other more widespread postural responses (e.g., his stance in readiness to strike), and respiratory changes (e.g., his shallower but more rapid breathing).

Inattention. Since we are attending to something most of our waking time, to say that a person is inattentive is really a shortened way of saying that he is not attending to the object which we wish him to be directed toward. At one time inattention was treated by parents and teachers as a behavior problem, to be overcome by exhortations to pay attention and by threatened or actual punishment. This manner of dealing with the problem rested upon the belief that "paying at-

ATTENTION

tion" was an ability that children could turn on and off at will and that therefore the child's "will" was the factor in the situation which needed changing. This belief has given way very largely in theory but, as yet, to a lesser extent in practice, to the conception that the degree of attention actually given is closely related to the importance which the subject places upon the details of that which is presented to him, and upon his ability to understand and grasp those details. Newer educational practices therefore consider inattention as a curricular, rather than a behavior, problem, and seek to gain the maximum of attention by allowing pupils to pursue studies of interest to them which are at the same time neither below nor above their intellectual level. It is believed that reward and punishment may bring the outward aspects of attending but will fail to bring the awareness and insight into relationships in the material to be mastered which genuine attention often creates.

Attention is therefore no longer measured by the posture of the pupil and the concentration of his eyes upon the speaker, the book, or the chart, but by such more active responses on the part of the learner as making connections with his own past experience and with other in-school and out-of-school activities, by puzzlement when a new fact does not seem to fit in with previously acquired learnings, and by readiness to continue working on a problem even when the class period is over.

In those schools in which the kind of attention demanded was of the passive variety, it was often concluded that the *attention span* of young children is extremely short and that therefore different lessons must follow each other in rapid succession lest inattention be the result. Many lessons in the first grade were planned for no more than ten or fifteen minutes at a time. While it is true that the attention span increases with age, it is also true that at any one age attention span varies greatly with the complexity of the task and the interest which it holds for the learner. Even kindergarten children, when engaged in an activity of their own choosing, can often be seen to participate in it for an hour or more at a time.

Teachers have often asked what features in instructional material will maintain attention on the part of the majority of their

students. There are few such features that can be isolated aside from the two already mentioned—the degree to which the material seems important to the student and the degree to which he can understand it. There is evidence, also, that variety and good organization are favorable for holding attention. However, mere variety which does not form part of an organized whole may bring superficial attention to one thing after another without the active connection-making that is described in a previous paragraph as being the sign of attention. Also, with regard to organized material, certain types of organization may lead to easy distraction. When facts are logically organized into formal series (so frequent in geography, for instance, where the rivers of the country are named in order of size, then the cities, then the industries with their products, etc.) each fact takes on the aspect of a separate item disconnected from the next. Each of these disconnections forms a breaking point where attention is easily diverted in another direction. On the other hand, where the material has more weblike interrelations, there may be an "unfinished" feeling on the part of the learner until he has dealt with it up to a certain point. Experiments suggest that there is a tendency to keep in mind and to resume tasks which have not been completed. The complexity of the interrelationships should, of course, be suited to the intellectual level of the student. Too much interrelationship may be as harmful to the holding of attention as too little.

Since inattention may be a result of fatigue as well as of lack of interest, schools are concerning themselves with the health of their pupils, with the full daily schedule of their lives, and with the physical environment in which the learning is done. Observation and investigation have also shown that inattention may be the result of the pupil's present concern with some matter other than that which is before him to be learned. Preoccupation with personal worries and fears not at all related to the classroom situation cannot be dropped by the child just because it is now time for history or arithmetic. In such instances, the treatment for inattention is an adjustment of the social and personality difficulties which are bothering the learner. (See MENTAL HYGIENE.) B.B.F. and B.B.M.

ATTITUDE. The term *attitude* has not been and probably cannot be distinguished clearly from such terms as *trait* (*q.v.*), *opinion*, *disposition*, *interest*, *value*, and *temperament* (*q.v.*). Most often it is used to describe an emotional reaction, either favorable or unfavorable, toward some object or class of objects, material or conceptual in nature. Attitudes are commonly assumed to direct behavior where it is expressed in appreciations, preferences, or values. A certain attitude toward a particular race represents the person's general disposition to act, speak, or think when confronted by actual situations involving that race. Since any one situation usually involves more than one attitude, with some reinforcing each other and others conflicting, the resultant behavior can rarely if ever be attributed to a single attitude.

Interest in the effect of education on attitudes and of attitudes on learning has led to numerous devices for their measurement. As yet, attitude-measuring instruments are largely verbal. They depend upon the person's own statement of how he feels, what he likes, what he does not like, and what he would do in a given set of circumstances. A large number of attitude scales have been patterned after the Thurstone method, which presents the subject with a list of statements of varying degrees of favorableness-unfavorableness toward the attitude-object (war, communism, temperance, the church, etc.). The subject checks those with which he agrees. Since each statement has already been assigned a scale value derived from the average degree of favorableness which a group of judges thought it showed toward the attitude-object, it is simple to compute an individual's score as the average of the statements he has checked. Examples of attitude-test items are: "War can never be eliminated from the world"; "War tests a nation's real worth"; "I would never go to war under any circumstances." Multiple-choice questions listing different possibilities of action are another method commonly used. Each choice is meant to be indicative of a certain type of value, e.g.: "If I had a million dollars to donate to a worthy cause I would (1) found

a home for orphans (social), (2) build a church (religious), (3) subsidize scholarly research (scientific or theoretical)." In this test, too, individual numerical scores may be obtained.

The best known device for measuring group opinion is the Gallup Poll of Public Opinion. Here a sample of the population is asked to give a "yes," "no," or "don't know" response to some current controversial question. The responses given in each category are added, turned into percentages, and quoted as attitudes representing the population at large. In certain instances the same question has been repeated from time to time and changes in attitude have thus been measured.

Group methods are also used to measure the attractiveness of various subjects of the curriculum, various books, and various teaching devices. Asking students to rank subjects, books, etc., in order of preference is as popular a device as asking them to respond in terms of their liking and dislike of specified subjects, books, etc.

Numerous studies have shown that there is some relation between verbal attitude and behavior, though this differs with different persons. Studies have also shown that verbal attitudes can be changed deliberately by teaching. Movies, stories, discussions, and excursions have produced some effect in the direction intended, although not with every student. It has also been found that in the cases of deep-seated attitudes, though verbal attitudes change, behavior remains substantially the same. The school therefore has become deeply interested in the origin of attitudes so that unfavorable attitudes may be prevented from arising. It has been found that attitudes are so much the result of the mores, especially the mores surrounding the individual when he is young, that adult education is a necessary concomitant to the attitude-training of children. The successful building of desired attitudes and loyalties in the young through having them permeate every phase of the culture is exemplified not only in the Fascist countries but also in the race discrimination of the American South. The Fascist countries also have taught us not to underrate the influence of verbal propaganda on attitudes. That the same verbal propaganda may have opposite effects on different

persons is itself an indication that one's present attitudes determine the manner in which one assimilates new influences.

That attitudes toward learning and scholarship will have an effect on learning is obvious. Interest in, and the prestige value of, different subjects also influence achievement in those subjects. Attitudes of conservatism, of race prejudice, of internationalism, to name only a few, may have a qualitative effect on what is learned. During the last decade it has come to be accepted that the attitudinal frame of reference conditions not only the subjects to which the learner will pay more attention, but also the kind of relations seen in, and deductions made from, the factual material at hand.

ATTITUDE THERAPY—See PSYCHOTHERAPY.

ATYPICAL CHILD. The term *atypical child* has been used to refer to the child who is different from most children. It is difficult, however, to describe a child as an atypical child, for a child is rarely atypical in all his characteristics. Rather than refer to him as an atypical child, it is better to describe him as a child who is atypical in intelligence, or in honesty, or in school achievement, etc.

The word *atypical* often conveys an unwarranted unpleasant connotation. All that it should imply is a deviation from the average; a brilliant youngster is as atypical as a dull one. Investigations have revealed that with regard to the majority of measurable characteristics — height, intelligence, school achievement, honesty, emotional adjustment, etc.—human beings differ from each other in such a way that their scores or measurements on these characteristics distribute themselves approximately according to the normal probability curve (*q.v.*). This means that most scores are clustered about the mean and that the farther a score is from the mean the

fewer will be the number of persons who have the trait to the degree represented by that score. For any one trait that is distributed according to the normal probability curve, the scores in that trait of about 68 per cent of the population should lie within the limits set by a point one standard deviation above the mean and one standard deviation below the mean. This is usually regarded as the range of normality and any person who has a score within that range is regarded as normal or typical with respect to that trait. Beyond these points in either direction, atypicality begins. There are therefore both positive and negative atypicalities and varying degrees of each. (See EXCEPTIONAL CHILD.) B.B.F.

AUDIO-VISUAL AIDS. Audio-Visual Aids are those which assist the pupil to gain correct concepts through visual and auditory presentation of concrete learning material. Recent technological advances such as the sound motion picture, the radio, and improved projection apparatus have made available to the schools the means for realistic perceptual learning. The fundamental ideas behind the use of audio-visual material is, however, as old as the earliest drawings of the cave man or a demonstration of how to club little, wooly horses. Over-enthusiasm on the part of some who sponsored the use of visual presentations caused the term *Visual Education* to be applied to the use of this material. As a result, there was created the false impression that this was a special kind of education, apart from and superior to the other forms of education. Other enthusiasts have applied the term *Sensory Aids* to include the valuable exercises of touch, taste, and smell. A growing number of teachers are using the term Audio-Visual Aids to mean the use of pictures, records, radio and the like as an adjunct to other school experiences and as true "aids" to learning. In this sense the term is used broadly enough to include other sensory experiences which may add to the concreteness of the learning situation.

Among the aids which are now available are pictures, graphs, cartoons, maps, blackboards, bulletin boards, charts, dramatics, models, specimens, posters, motion pictures, film strips, stereographs, slides (including the increasingly popular 2x2 inch slides in color), and field trips. The usual equipment

AUDIT, SCHOOL — AUDITORY AIDS

for the preservation and presentation of such materials includes a picture file, usually ledger size; an *Opaque Projector*, sometimes called a *balopticon* or *reflectoscope* which projects any picture from a book, magazine, or other source; a *Film Strip Projector* which is used for showing a series of still pictures printed on a positive strip of 35mm film; a *Stereoscope* which is a viewing instrument with two pairs of lenses through which photographs taken in pairs from slightly different angles appear to have depth; a *Motion Picture Projector*, usually in the 16mm size since most educational films are available in this size, and preferably a sound machine since both sound and silent films can be shown on a sound projector. Some schools will have a *Microprojector* for projecting enlarged images of specimens, microscopic slides, and the like. Among the more common auditory aids are the sound motion picture projector; the playback machine or phonograph, the former being increasingly made in the dual speed model which plays both the regular phonograph record at 78 RPM (Revolutions per minute), and specially prepared records (16 inch) which play at the rate of $33\frac{1}{3}$ RPM, and on one side of which a 15-minute program may be obtained; recording apparatus for making records of student voices, or recording speeches and other radio presentations; finally most schools are now equipped with radio receiving sets.

Fairly satisfactory methods have been developed in the utilization of auditory and visual aids but much experimentation needs to be done in this area. The recommended methods include careful selection of materials, a preview or preliminary examination of the material prior to class presentation, and the proper placement of the material in the lesson with adequate preparation and follow-up. Properly used, auditory and visual aids should stimulate discussion, exploration, and creative effort. (See such articles as AUDITORY AIDS; DRAMATICS; JOURNEY, SCHOOL; MOTION PICTURES IN EDUCATION; RADIO EDUCATION.) W.H.H.

AUDITORIUM EXERCISES—See ASSEMBLY, SCHOOL.

AUDITORY AIDS. The principal auditory aids in use in schools today are radios. (See RADIO IN EDUCATION), phonographs, recorders, sound motion pictures (See AUDIO-VISUAL AIDS), public address systems, and central sound systems.

The phonograph is a comparatively inexpensive piece of equipment which may be used in connection with a large variety of subjects. A recent catalogue of recordings (J. ROBERT MILES, *Recordings For School Use*, World Book Co., New York, 1942) lists hundreds of available records. The modern recording comes in two sizes: the regular phonograph record which plays at 78 revolution per minute (RPM) and the transcription which plays at $33\frac{1}{3}$ RPM. Phonograph records may be obtained in six, eight, ten, and twelve inches in diameter, but most commercial transcriptions are sixteen inches in diameter. A sixteen inch, $33\frac{1}{3}$ RPM transcription offers a thirty-minute program, fifteen minutes on each side of the record. Transcriptions offer the additional advantage of more perfect reproduction of sound than do the phonograph records. According to a recent survey made by the U. S. Office of Education the number of record players operating at $33\frac{1}{3}$ RPM is rapidly increasing in the high schools of the United States. It would seem, therefore, that the best equipment for the playing of records in schools would be a dual-speed machine capable of reproducing records at 78 RPM or $33\frac{1}{3}$ RPM. Several such machines are now on the market.

Methods of using records in the classroom correspond very closely to those used with the radio. The record possesses the advantage, however, of being readily available. The teacher can listen to it, prepare a plan for its use, and gather supplementary materials to augment the information contained on the record. It can be introduced into the program at the time when the pupils feel the

need for such material, and it can be repeated either for the entire class or for individual or small group listening. To assist teachers in the use of recordings the American Council on Education has set up a Recordings Division, New York University Film Library, Washington Square, New York, N. Y.

If the school is equipped with a recording machine it may make many of its own records. Speeches may be transcribed from radio broadcasts; student plays and music presentations may be recorded; voices may be recorded for speech improvement; and many other uses will occur to the educator.

The sound amplification system or public address system is being installed in many schools. The portable unit which may be used in the auditorium, from one classroom to another, or on the athletic field and playground, is favored by many schoolmen. Many sound motion picture machines possess microphone jacks and may be used as public address systems. In addition central-sound systems are now being installed as standard equipment in new schools. Notices, announcements, choral music, plays, and other programs may be broadcast over these systems. The centralized-sound system constitutes a local broadcasting unit and, properly used, may be an important adjunct to the school's auditory aids.

AUSTRALIA AND NEW ZEALAND, EDUCATION IN. Education in Australia and New Zealand, like most of the cultural phenomena in the two South Pacific democracies, has the marks of recent construction. There are few hallowed institutions or shackling traditions in the Antipodes, and where they exist they have been imported from England rather than grown on the spot. This is not because the Australians and New Zealanders have ever lacked education, but because of the fact that until a little over a hundred years ago the area was almost completely uninhabited.

Systematic English settlement of Australia began in the early years of the nineteenth century, and the first landings of settlers in New Zealand took place in 1840. The settlers were highly selected. They had undertaken a longer journey than had any other group of migrants, seeking economic opportunity, individual freedom, and political democracy. Education played an important part in all of their schemes to establish a new society which would retain only the best features of the English society they had left. The settlement of Australia and New Zealand was contemporary in time and similar in character to the peopling of the western United States. Attitudes of frontier individualism appeared, though not to the same extent as in the North American West. One important difference existed: Australasian settlers had come directly from England, many with urban industrial experience. From the beginning their plans included the establishment of substantial cities, and they took more kindly to order and regulation. In both countries the coastal areas are highly productive and the interior relatively barren, resulting in an urban concentration of population. In 1940 almost half of Australia's 7,069,000 persons were found to be living in the six state capitals, which are coastal ports. New Zealand, twelve hundred miles east of the continent, has a similar concentration in its four largest cities.

The early schools began, as in the United States, under a variety of local bodies and church organizations. Instead of awaiting the slow evolution of local systems, the Australasians made a radical departure—education was centralized under national and state governments.

The state system, dating from the adoption of free, compulsory, and secular education about 1875 in both countries, brought the speedy and uniform extension of schools in the cities and in "backblocks" or agricultural frontiers of Australia and New Zealand. Teachers' organizations played a part in some of the steps toward centralization. These organizations are variously known in the six Australian states and New Zealand as Unions, Federations, or Institutes, and they are strong everywhere. The proportion of men in the teaching force is high compared with the United States, as high as 56 per cent in some of the Australian states. Ad-

AUSTRALIA AND NEW ZEALAND

ministration by the central government was favored by the teachers' associations, since it removed the vagaries of local politics from the field of education, stabilized salaries, and facilitated promotion by permitting freedom of movement from one locality to another within a uniform nationwide system.

Attendance at a public school or at one of the few approved private schools is compulsory from the age of six, but most pupils enter at five years of age. The school year is long, approximately 41 weeks, and the mild climate permits a high average attendance. Although compulsion ceases at 14 years, 50 per cent of the children continue in high school. The primary school with two or more "primers" or preparatory classes, and six "standards" is comparable in organization to the American elementary school of eight grades, but it is not normally articulated with a high school. The abrupt transition from primary to secondary school is made at the age of thirteen years. Coeducation is universal in the elementary schools and is common in the high schools, though there has been a tendency in Australia in the recent past toward separate boys' and girls' high schools.

The high schools are noteworthy for their isolation from the elementary school system and their emphasis on thorough academic training. Languages are given a more prominent place in the curriculum than seems justified by the infrequent contacts with Europe, and pure mathematics has a central position. Many of the older high schools have emulated the English public schools, with boarding establishments for students comparable to the dormitories of American private colleges. School uniforms for both boys and girls and academic gowns for the faculty are general in the high schools.

A separate corps of inspectors, often recruited from the elementary school inspection force, carries out administrative decisions of the central department relating to high schools. As in the lower schools, the inspector's annual report on each teacher is the basis for promotion. The stimulation of new ideas and teaching practices is also a designated task of the inspector, but the work of assigning grading points to all teachers in a large territory limits him mainly to measuring the teachers' skills by testing the students. This system has led to uniformity among

schools in curriculum matters and a high level of achievement in subjects that are adapted to testing.

The agricultural, technical, and teacher-training institutions are well developed in Australia and New Zealand. The organization of agricultural and technical high schools parallels that of the nontechnical institutions, and in New Zealand the two agricultural colleges are part of the university system. The teacher training colleges are supported entirely by government funds, and in New Zealand the students are paid the salary of beginning teachers during their two years of attendance at the training college. In addition they are given special tuition scholarships at the university and a release from training college classes that conflict with classes in the other institution, so that they can complete the work for a degree and a teaching license at the same time. These advantages for teachers in training create competition for admission, and cause a channeling of the highest talent into the teaching profession.

The college and university systems of Australia and New Zealand follow the English rather than the American or European patterns. In New Zealand a considerable part of the government contribution comes to the university colleges by way of "bursaries" or tuition scholarships provided for all students who have a good scholastic record. In this way the government ensures free college and university education for the talented, regardless of their ability to pay. The courses offered in the university colleges are relatively few in number, the work in each course more intensive, and the units of study longer than in the corresponding American institutions. The students at admission and at graduation are older. There are fewer disciplinary restraints; the elected officers of the students' associations wield considerable influence in their negotiations with the faculties or "professorial boards," which have the functions usually assumed in America by college presidents. Annual written examinations, generally external, dominate the colleges at every stage. Students who fail in these examinations can, and commonly do, remain freshmen for administrative purposes throughout a career of several years.

Most of the important differences between education in Australasia and in the United States are due not to any difference of subject

matter or methods, but rather to centralization and the greater equality of opportunity associated with the even distribution of incomes in Australasia. The graduate from Australia or New Zealand has been offered less variety in his educational fare, but he has studied with more intensity in his narrower range of subjects. He has been submitted to more external examinations, and he has emerged with all the advantages and handicaps of a system that has uniformity and thoroughness as ultimate goals. In the past five years important movements seeking a reorientation have gained momentum with the developing popular enthusiasm, inspired by English and American examples, for "new education." The Educational Research Councils, starting with grants from the Carnegie Corporation of New York, have provided the means of expression through publications of high quality and permanent value. In essence these movements are a revolt against bureaucratic narrowness and formalism, and the direction of the reorientation is toward diversified flexible curriculum, better school-community relations, and the new education. If these qualities can be imparted to the efficient and democratic systems of Australia and New Zealand, the two countries will lead in the field of education as they did in social security legislation. AUTHORITARIANISM. The determination of a point of view by outside forces, such as custom and a revered person or institution, is known as authoritarianism. For instance, some educators hold that subject matter that has lasted a long time or has been recommended by church leaders or school administrators as constituting the fundamentals should be required of all pupils. Similarly others, believing that reality, or truth, exists outside the learner, would prescribe courses in a particular form, which the learner would be expected merely to mirror, or reflect. Indeed any gap that educators create between the child and the curriculum is an expression

of authoritarianism. The tendency of modern public education is in the opposite direction: toward affording the pupil practice in creating, evaluating, choosing, planning, and acting intelligently. (See also AIMS OF EDUCATION and such items as ACTIVITY PROGRAM, CURRICULUM, DEMOCRACY AND EDUCATION, DISCIPLINE, PROGRESSIVE EDUCATION.)

W.A.S.

AUTONOMIC NERVOUS SYSTEM—

See NERVOUS SYSTEM.

AUXILIARY CLASSES.

Auxiliary classes are often known as ungraded classes, special classes, or opportunity classes and exist for the purpose of providing individual attention to atypical children without regard to their grade levels. Usually the classes are for pupils who are below normal in their performance because of physical or mental defects, but a few schools have organized special classes for brighter pupils. There is no substantial agreement either on the success of such classes or on the types of pupils to be cared for in them. (See EXCEPTIONAL CHILD; GIFTED CHILD, EDUCATION OF; SPECIAL CLASS.) J.E.G.

AVIATION AND THE CURRICULUM.

In 1938, officials of the United States Government in charge of aviation became concerned over the fact that not enough young Americans were learning to fly. Convinced that the superior air power of Germany had been responsible for the Munich Pact, officials of the Civil Aeronautics Administration under the leadership of Robert H. Hinckley, Assistant Secretary of Commerce for Air, called a meeting of college and university presidents to consider this gap in American education and to decide on a democratic approach to the problem.

As a result of this meeting, there was born the Civil Pilot Training Program (hereinafter called the C.P.T.P.) of the Civil Aeronautics Administration (hereinafter called the C.A.A.). It was inaugurated in more than 700 institutions of higher learning in 1938. The C.P.T.P. was financed by federal funds paid to the colleges, which in turn arranged with near-by commercial flying schools to

conduct the flight training under federal contract. These flying schools had to meet minimum standards set by the C.A.A. Thus before the invasion of Poland, largely as a result of the vision and leadership of American government and university officials, the C.P.T.P. became an established phase of American higher education. In 1938, prior to the operation of the C.P.T.P., there were only 23,000 licensed pilots in the United States. In 1941, after three years of operation, this number had expanded to 100,000, but even this fourfold increase was inadequate in comparison with the needs of the day.

The Japanese attack on Pearl Harbor in December, 1941, served to dramatize the fact that the United States would have to become a nation of flyers if it would win the war and maintain the peace to follow. "Air-conditioning" America became a major problem of the federal government. Already C.A.A. officials had studied the German plan for promoting aviation by means of the German Ministry of Education. In 1942, after conferences with Dr. John L. Studebaker, United States Commissioner of Education, the United States Office of Education pooled its resources with the C.A.A. and organized the Joint Committee on Aviation Education of the Civil Aeronautics Administration and the U. S. Office of Education under the chairmanship of Dr. Ben D. Wood of Columbia University. Other members of the Joint Committee were Dr. Nickolaus L. Engelhardt, Dr. Paul R. Mort, and Dr. George T. Renner, all members of the faculty of Teachers College, Columbia University.

This committee undertook to devise a plan for extending aviation education downward to the secondary and the elementary schools, and for preparing the curricular materials which such a program would make necessary. The Air Training Corps of America (hereinafter called the A.T.C.A.) was organized early in March, 1942, on the secondary school level, with fourteen experimental units in and around New York City to provide preflight training for boys between twelve and eighteen years of age. The U. S. Army Air Forces detailed Lieutenant Colonel S. J. Donovan to supervise the preparation of the A.T.C.A. training program, and to synchronize it with the needs of the Air Forces Training Command. By September, 1942, the A.T.C.A. had 500,000 boys under training in schools and

boys' clubs all over America, operating in carefully developed units with instruction curricula from A.T.C.A. headquarters. On that date, its direction was taken over by the U. S. Office of Education and preflight training courses were instituted in every secondary school throughout the nation as part of the High School Victory Corps. The curriculum of these preflight courses consists largely of the following: airplane structures, aerodynamics, airplane engines, meteorology, communications, air navigation, human factors in flight, and physical fitness. In the meantime the goal of the U. S. Army Air Forces had been set at 2,000,000 men by the end of spring, 1943.

Besides Lt. Col. Donovan, three men were largely responsible for the development of the A.T.C.A. training program: Dr. Paul R. Mort, member of the faculty of Teachers College, Columbia University; Clayton Knight, World War I flyer; and Arthur Loew, executive of Loew's Incorporated, in charge of national promotion.

Parallel with the work of the A.T.C.A. program, an Aviation Education Research Project was organized under the direction of Dr. Nickolaus L. Engelhardt, member of the faculty of Teachers College, Columbia University, to prepare aviation materials for all phases of the secondary school and elementary school curriculum. In March, 1942, specialists in each of the major curricular areas were selected to engage in research and write instructional materials for use in the schools. By July, 1942, the Air Age Education Series was in press; by September, 1942, the Macmillan Company made the books available to local school systems throughout the United States. A record had been set in the publishing world.

The Air Age Education Series touched on every significant aspect of the existing school curriculum affected by aviation: Physical Science, Geography, Social Studies, English, Mathematics, Biology, Industrial Arts, and Health Education in the secondary schools; and Science and Geography on the elementary level. Concurrently, specialized curricular materials for the preflight training courses also were developed. Two separate research units attacked this problem: the Aviation Education Research Group of Teachers College, University of Nebraska, and the Aviation Education Research Group of Teachers

College, Columbia University. Following closely the Civilian Pilot Training Manual utilized in the college training program, these groups wrote texts suitable for use in aeronautical training on the secondary school level. The entire Air Age Education Series was thus the cooperative result of numerous education specialists.

At the same time that this research and experimentation were being carried on, regional, state, and local conferences on aviation education were attended by local and state school administrative officials meeting with C.A.A. experts and administrators. The conferences sought to determine the best way of introducing these curricular changes and adaptations into the schools of the nation. Of prime importance were the instructional talks on the new geography of the air age given by Dr. George T. Renner, Professor of Geography at Teachers College, Columbia University. Throughout the spring and summer of 1942 these conferences were held in every area of the United States. By September, 1942, every local school system had developed some plan for meeting this urgent new need, and aviation education was introduced as a significant phase of American public education. All of this was achieved on a voluntary, cooperative, democratic basis.

During the summer of 1943, teacher training courses in all aspects of aviation education were inaugurated in colleges and universities throughout the United States, financed with federal funds from the C.A.A. Thus by September, 1943, aviation became an established and significant phase of American edu-

cation on the elementary, secondary, college, and professional levels. (See AERONAUTICAL EDUCATION.) R.N.C.

AVIATION EDUCATION—See AERONAUTICAL EDUCATION; AVIATION AND THE CURRICULUM.

B

BACCALAUREATE. The word "baccalaureate" is derived from an eighth-century term meaning a stock-farm assistant and was later sometimes considered as a corruption of terms meaning laurel-bearer. Originally it referred to a student not yet master of the arts—i.e., of "the seven liberal arts" and accompanying preliminary studies—in the early Middle Age universities. From the same root probably came "bachelor," which originally meant a young knight serving under an older one's colors. The baccalaureate or bachelor's degree also originated in the Middle Age universities. It indicated the completion of general studies and the ability to study further to become a master or teacher.

Today the term "baccalaureate" is used to refer both to a degree and to the farewell sermon preached to a college graduating class. The baccalaureate or bachelor's degree is the first degree given by colleges in the United States, England, and many other countries. As a rule, in the United States it means four years of study beyond high school or preparatory school, and implies both general study of several fields and more concentrated study of one field. If the latter field is a natural science or so-called vocational field like home economics, the degree is usually bachelor of science (B.S.); if one of the social studies or humanities, it is usually the degree of bachelor of arts (B.A. or A.B.), sometimes bachelor of philosophy (B.Ph.); if law, bachelor of laws (LL.B.). For the past fifty years there has been a trend toward the granting of only one degree for all undergraduate study, whatever the field of specialization: the B.A.

Bachelor's degrees have been somewhat standardized by the efforts of various accrediting agencies. Graduate schools throughout the world examine and exchange notes concerning the qualifications of the colleges from which their students seek to enter. Accrediting associations examine not only the colleges in their regions but also the secondary

schools. The legal, medical, teaching, and other professions set entrance examinations or course requirements which help colleges to maintain proper standards. (See ACCREDITING.) The University of Chicago almost alone has just decided (1942) to give the bachelor's degree after two years of general study in order to have it signify only a general education and to eliminate students who do not have aptitude for advanced concentrated study. Many critics believe, however, that with an ever higher average age for vocational employment and ever more complex studies, fewer students will be content to leave college at the end of their second year. (See DEGREES.) M.G.F.

BACONIAN METHOD. Francis Bacon's formulation of the inductive method for the advancement of learning was of great educational significance. Bacon did not invent the inductive method of reasoning—it is as old as the human mind itself. He did state the procedures under which inductive reasoning should operate in order to be efficient: the removal of prejudices, the thorough observation by the senses, the careful tabulation of cases, the study of exceptions as a check, the formulation of the generalization. Although Bacon himself did not apply his inductive procedures to school methods, his writings paved the way for the later use of observation and experimentation in classroom teaching; for the study of facts as the beginning of the thinking process; for the selection, comparison and classification of examples and instances; for the placing of emphasis upon the problematic approach to learning. BAPTISTS, EDUCATIONAL WORK

OF. The interest of Baptists in formal education in America stems from scholarly sources in England and the continent of Europe. The two most prominent Baptist founders of American colonies, Roger Williams, of Providence, and John Clarke, of Newport, were more or less learned men. Roger Williams not only answered his public critics in able language and logic, but prepared a lexicon of the dialects of the New England Indian tribes, basic for all later Indian dictionaries. Dr. John Clarke was a lawyer and physician before he was a preacher, and had, of course, scientific training. Many of the governors of the colonies and their henchmen were well trained.

The real beginnings of formal education in the American colonies were in the little village schools fostered by the churches and financially supported by the families, and usually located near the village or town churches. The more ambitious attempts at higher and broader education by Baptists occurred about the beginning of the 18th century. In 1719, Thomas Hollis, a Baptist in London, England, founded two professorships and ten scholarships for poor students in Harvard College. The Philadelphia Association, in 1722, proposed that the Baptist churches search for young men of promise for the ministry, in order to educate them. A Baptist Education Society was formed at Charleston, South Carolina in 1775; and in 1789, the Philadelphia Baptist Association gathered a fund for the education of prospective young preachers. The Warren Baptist Association, Rhode Island, did the same thing in 1793. These initiatives were fruitful in the establishment of Rhode Island College, later Brown University, the first Baptist College in America.

The Baptists had three classical academies in 1775, one at Hopewell, N. Y.; one at Wrentham, Mass.; and one at Bordentown, N. J. The establishment of these schools naturally bred the desire among the professional and other intellectual classes for schools of college grade. Rhode Island College (Brown University) was established twelve years before the War of the Revolution ended and had graduated seven classes by that time. In the early days of the 19th century, other Baptist institutions of education arose, more or less

disconnected and local, but which, for decades, were a powerful denominational influence, e.g., Waterville College, Maine, now Colby University; Madison College (N. Y.) now Colgate University; Denison University and Kalamazoo College. In the latter half of the 19th Century came various smaller but useful colleges in the Middle and Far West: Shurtleffe, Ottawa, Sioux Falls, Linfield, Redlands, et al. Bracketed with these should be several theological schools still in existence and going strong—known in earlier days as Newton Theological Institution, Rochester Theological Seminary, Colgate Theological School, Crozer Theological Seminary, Southern Baptist Theological Seminary and Berkeley Baptist Divinity School. In the Southern states, schools and colleges for both whites and Negroes sprang up rapidly from 1850 on.

The greatest impetus to education, however, both general and specialized, among Baptists in all America, came after the founding of the General Education Board in New York about 1903. While this Board was not sectarian, nor limited in its beneficence by any restrictions of race, color, or creed, nevertheless, since Mr. Rockefeller, the founder, was a Baptist of great prominence, it was inevitable that Baptist prestige should be enhanced because of his name. The work of this Board was for the benefit of many kinds of worthy institutions large and small, for whites, Negroes, and Indians. On the other hand, Mr. Rockefeller, a few years before, had founded the great University of Chicago, with its prominent faculty, its graduate schools, its large funds, and its rapid growth, as the last word in education to date. Not only was the founder a Baptist, but the organizer and first president, Dr. William Rainey Harper, also was a Baptist, as were a majority of the trustees. These circumstances not only publicized Baptist prestige in education, but greatly influenced education in general among individuals and communities. For the past 50 years Baptist education has flourished. At the present time there is a tendency among the largest Baptist institutions to relinquish denominational control in the best interests of the colleges themselves, on account of their very diversified students and alumni. The oldest Baptist University, Brown, and the largest, Chicago, have altered

their charters to that effect.

With the great educational and missionary upsurge in the United States about 1840, Baptist educational interests became widespread. It was the beginning of an era in the establishment of railroads, newspapers, and academies throughout the Middle West as well as the East. The American Baptist Home Mission Society inaugurated mission schools for Negroes and poor whites in the south, and the American Baptist Publication Society issued religious literature in great amounts and founded Sunday Schools in the pioneer areas of the West. These societies not only are now at the height of their careers, but have accumulated great endowments. In this work they have been ably seconded by the Woman's American Baptist Home Mission Society. Among the educational institutions fostered by the above societies, some have become famous, e.g., Spelman, Morehouse, and Bacone Colleges; Shaw and Virginia-Union Universities, and Kodiak School. Much of the supervision of schools and colleges heretofore exercised by these societies now has been transferred to the Baptist Board of Education.

The emergence of the Board of Education of the Northern Baptist Convention, founded in 1911 and incorporated in 1920, and succeeding the American Baptist Education Society, established an advantageous system of coordination, and was made possible by the formal unification in 1907 of all the Baptist interests north of the Mason and Dixon Line. This Board is concerned with (1) the maintenance and development of the schools and colleges under Baptist control, in the North for the most part, and a few in the South; (2) the stimulation of interest in the Christian Education of children and young people; (3) maintenance of religious interests among students, and (4) the development of missionary interest in the churches. The sponsorship of the Board embraces 18 colleges and universities, 12 junior colleges, 11 academies in the North; and 10 colleges and schools for Negroes in the South. In addition there are 10 theological seminaries. During the past 35 years, the real property assets of these institutions have grown to approximately \$90,000,000, with endowment funds of over \$125,000,000. University pastors and student counselors are maintained in about 140 institutions,

both Baptist and non-Baptist, for the benefit of Baptist students there. Baptist schools and colleges at the present time have about 2,500 teachers and over 35,000 pupils. Bacone College, Oklahoma, is the only institution of college grade for Indians in the United States.

The Missionary Education Department of the Baptist Board of Education is very important in general education, since there is a close relation between its work and the loyalty of Baptists to their general educational institutions, and the atmosphere therein. This department conducts schools of missions in churches and assemblies; mission study classes; and reading circles of nearly 300,000 members who read 1,500,000 volumes, collectively, every year. It distributes almost countless other books, and organizes competitive educational undertakings. It maintains several missionary and cultural organizations for the young people of the churches: The Worldwide Guild, for young women, with 40,000 members; The Children's World Crusade for boys and girls, with 50,000 members; and The Royal Ambassadors, for boys, with about 15,000 members.

Besides the educational institutions already described, the missionary societies of the North maintain six training schools for general missionary and church school workers. These schools enroll about 200 students and have real estate and endowment funds aggregating about \$1,300,000.

The American Baptist Publication Society, now 118 years old, maintains strong and varied activities. It issues scores of religious books annually, the Year Books of American Baptists, about 150 Sunday School and other periodicals; and maintains branch stores in various cities of the United States and Canada. It supports *colporteur* work, chapel cars and boats; establishes Sunday Schools and Vacation Bible Schools, summer assemblies and camps for Christian culture. It engages also in Americanization work.

In the Southern Baptist Convention, which separated from Northern Baptists in 1844 over matters of policy, much the same categories are maintained as in the territory of Northern Baptists. Their Education Commission lists 12 academies, 24 junior colleges and 26 full colleges, besides 3 theological schools. In the missionary classification there are enrolled 24,629 Sunday Schools and

7,000 vacation Bible schools. Their "Sunday School Board" maintains a large publishing establishment, similar to the American Baptist Publication Society in the North.

While the Negro Baptists, both North and South, who are several million strong, have a general interest in the maintenance and management of Negro education, for the most part those which are particularly successful are under the aegis of the white educational and missionary groups.

In Canada, while the scope and spread of all forms of personal and public education have not increased as rapidly and as extensively as in the United States, nevertheless the results have been highly satisfactory. Among the Baptist colleges and universities credited to Baptists in the Dominion, Acadia College in Nova Scotia and McMaster University in Hamilton, Ontario, are the best known. Many students from these and other institutions pursue advanced studies in the universities of the United States.

Cultural aspects of Baptist education should include the historical societies and libraries, and the distinctly Baptist periodicals. The American Baptist Historical Society at Crozer Theological Seminary, Chester, Pa., the Backus Historical Society at Newton—Andover Theological School, Newton Centre, Mass.; and the Samuel Colgate Baptist Historical Collection, at Colgate University, Hamilton, N. Y. all maintain excellent and large aggregations of Americana, with facilities for research.

There are more than 40 Baptist magazines and papers of recognized standing in the United States. Among the most prominent and successful, both North and South, are *The Watchman-Examiner*, *Missions*, *The United States Baptist*, *The Christian Index*, *The Christian Leader*, *The Ministry*, *The Pastor's News Letter*, *The Commission*, etc. Foreign tongue periodicals, also, are published by Swedish, German, Norwegian, Hungarian, Roumanian, Polish, Italian, French and Slovak Baptists.

Freedom of teaching has been distinctively recognized in American Baptist educational institutions for the most part, with only occasional exceptions. The Charter of Brown University, the oldest American Baptist College, provides definitely for such freedom.

Some Baptist individuals whose personali-

ties have loomed large in the field of Baptist education in America have been Francis Wayland (Brown), E. Benjamin Andrews (Brown), Benjamin Ide Wheeler (University of California), William R. Harper (University of Chicago), William H. P. Faunce (Brown), Augustus H. Strong (Rochester Theological Seminary), H. L. Morehouse (American Baptist Home Mission Society), Ernest D. Burton, Shailer Mathews (Divinity School of the University of Chicago), George E. Horr (Newton Theological Institution), John Hope (Morehouse College), John D. Rockefeller, and Ambrose Swasey (Denison)—all now deceased.

The Baptist World Alliance, organized in London, England, in 1905, includes Baptists of all countries. It holds its meetings once in five years, but meantime exerts a wholesome and material interest on the educational aspects of various Baptist institutions in such countries as Sweden, France and Australia. The missionary societies, especially of the United States, maintain academies, colleges and universities of high grade, in China, Japan, India, Burma, the Belgian Congo, and other lands.

BAR GRAPH—See GRAPHIC METHODS.

BARNARD, HENRY (1811-1900).

Henry Barnard was an active protagonist in the Common School Revival in the mid-nineteenth century. In this respect his significance is akin to that of Horace Mann (*q.v.*). In addition, however, he has often been called the scholar of the Revival. A third line of influence has stemmed from his persistent, and eventually successful, struggle to put the Federal government into the program of American education.

As a Leader in the Common School Revival. Barnard, as Secretary of the State

Board of Education in Connecticut and later as State Superintendent of Common Schools there, faced an educational situation similar in general to that confronting Horace Mann in Massachusetts. He strove to counteract extreme decentralization in school control, and to replace it by enlightened and informed state action. He worked also to vitalize local educational services, especially during the interregnum between his services to Connecticut when he was the first Commissioner of Common Schools Rhode Island had ever had.

In the implementation of his program, Barnard stressed the need for *better educated teachers*. The first institute for teachers was established by him in 1839, the work being conducted by Yale College professors and by Barnard himself. A traveling model school for these institutes was devised. A state normal school was established at New Britain, Connecticut. This catenation of contributions by Barnard places him in the long line of succession of those who have worked for an American program based on the postulate that those who would educate must themselves be educated.

His steadfast adherence to this postulate was later (1858) evidenced when as chancellor of the University of Wisconsin he organized a State Normal School in that state.

Barnard's program for a Common School Revival contributed much to the stirring of local initiative in the setting up of town libraries, and of town lectures for teachers and for the public generally.

As Scholar of the Revival. Barnard, from 1855 to 1881, edited the *American Journal of Education*, which one writer has called "the most encyclopedic work on education in any tongue." Another has characterized it as the beginning of an educational literature in America. In any case, it is an educational *magnum opus*.

In this work, Barnard interpreted European educational thought and practice for the information and serious thought of Americans. Its pages, supplemented by additional writings, made Pestalozzi (*q.v.*) better known here; they helped bring to American readers the humane and progressive treatment of juvenile delinquents developed out of the Pestalozzian educational philosophy by Fellenberg and others. The *Journal* also helped bring the philosophy of the gentle Froebel (*q.v.*) across the Atlantic, and helped ac-

quaint us with the underlying Kindergarten (*q.v.*) idea, developed in the United States by William T. Harris (*q.v.*).

As Advocate of a Federal Government Secretariat in Education. Barnard, in spite of the pressing problems confronting him in Connecticut and Rhode Island, never lost sight of his belief that some kind of federal agency was needed to keystone the American educational structure. He had hoped for a national Department of Education, cognate in its position with other such departments in the President's cabinet. What eventuated, in 1867, was the post of United States Commissioner of Education (*q.v.*), to head the Bureau of Education, a bureau of the Department of the Interior. Henry Barnard was appointed by President Johnson as its head. In spite of changes in nomenclature—it is now the Office of Education (*q.v.*)—the main lines of its work as charted by Barnard still direct the course of this important federal educational agency.

BATAVIA PLAN. The Batavia Plan, originating in Batavia, New York, was a type of classroom organization in which two teachers, one called the regular teacher and the other the assistant, taught large classes. It was an attempt to help pupils in their work so that all might make normal progress and be promoted regularly. Retardation was to be eliminated if possible. While the regular teacher carried on the usual class recitation, the assistant teacher helped the laggards. Recitation activity was reduced and more of the teachers' time was given to assisting pupils in their individual study. The bulk of the special help was given to slow-learning pupils. Modifications of the plan were made by other schools adopting this type of class organization, but the plan as originally devised did

not have wide acceptance in this country.

BIBLIOGRAPHICAL CENTERS. Bibliographic centers are a recent development resulting from cooperation among libraries for the purpose of coordinating existing library resources and permitting specialization rather than duplication in collections. Catalog cards for books in the libraries which contribute to the center are filed in the center, together with cards for books in the Library of Congress.

The public libraries of Philadelphia, serving as a center for all the libraries in that metropolitan area; the Denver Public Library, which serves the entire Rocky Mountain region; and the Pacific Northwest Bibliographic Center, located at the University of Washington, in Seattle, are the three in existence at present.

E.S.

BIENNIAL SURVEY OF EDUCATION. The Biennial Survey of Education, published by the United States Office of Education (*q.v.*), consists of articles and statistics concerning education throughout the United States. As various chapters are pre-

pared they are issued in a series of bulletins, which are bound together at the end of two years, making one or more volumes. Each of the chapters may be secured at a small cost from the Superintendent of Documents, Government Printing Office, Washington, D. C., or they may be seen in most public libraries.

Among the topics to be found in the Biennial Survey of Education are: Elementary Education; Secondary Education; Industrial Education; Homemaking Education; Agricultural Education; Music Education; Hygiene and Physical Education; Education of Exceptional Children; Adult Education; College and University Education; Professional Education of Teachers; Medical Education; Engineering Education; Radio in Education; Library Service; Review of Educational Legislation; Educational Research of National Scope and Significance. The Biennial Survey also includes statistics concerning State School Systems; City School Systems; Universities; Colleges and Professional Schools; Teachers' Colleges and Normal Schools; Public High Schools; Private High Schools and Academies.

W.V.N.

BILINGUALISM. In America the bilingual child, the one who speaks two languages, is most often the one who hears and speaks a foreign language at home while his schooling is conducted entirely in English. Since language facility is acquired much more through social communication than through direct study, children reared in foreign-speaking homes may never acquire an adequate mastery of English if their social environment outside the home is also one where the foreign language is the one primarily used, or where the English that is spoken is full of inaccuracies of grammar, pronunciation, and vocabulary.

There is some controversy as to whether children who are reared in two languages are handicapped by virtue of this fact even when both languages are used in social communication and both are adequately spoken by the adults. The handicap has even been said to extend to performance on verbal intelligence tests. Some psychologists differentiate between the effect that bilingualism has upon the bright and upon the dull, concluding that it may be of advantage to the former and of disadvantage to the latter. There is some evidence for such a generalization. Terman

found proportionately more children who rated in his genius group among the bilingual American Jews and Chinese than he found among children of English-speaking ancestry. Another relevant finding is that of Hoffman who set up a Bilingual Schedule to measure the amount of foreign language to which the child was exposed and in which he engaged. The Jewish children who formed one of the groups studied were superior to the Italian in a verbal group intelligence test, but equal to the Italian in the Pintner Non-Language Intelligence Test and also in the amount of bilingualism. (The quality of the foreign language spoken in the home was not measured.) Among the Italian children, those with the highest bilingual scores made poorer scores on English reading tests than did those with the lowest bilingual scores. Among the Jewish children, however, those with the highest bilingual scores made better scores both in reading and in verbal intelligence. There was no relationship between bilingualism and the non-language intelligence test used either for the Italian or for the Jewish children. More such studies are needed before foreign parents are advised, as is being done in many instances, that their children will only become confused if their home expects them to use a language other than English.

In any case, the school's attitude towards the child's foreign language should take into consideration the consequences of that attitude, not merely upon the child's mastery of English and of subject-matter taught to him in English, but also upon the social and emotional attitudes of the foreign children and their parents. Relationships between parents and children, feelings of foreign language groups towards the country of their adoption, adjustments between minority and majority groups, all need to be safeguarded. The English language must become, through the schools, a unifying rather than a separating force.

The U. S. Office of Education has initiated a number of studies to discover how English can best be taught to foreign-speaking children both in continental United States and in such territories as the Philippines, Hawaii, and Puerto Rico. Successful practices described range from specific English lessons embodying a variety of techniques to the incidental learning of English as the children go about the work and play activities of an

informal curriculum.

BIOLOGY, TEACHING OF—See SCIENCE, TEACHING OF.

BIRTH INJURY. Birth injury or birth trauma refers to an injury to the brain occurring during delivery. Such injuries happen more frequently in the first born, because first labor is usually the most prolonged and difficult, and in premature babies. They may result in convulsions, motor incoordination, speech defects, paralyzes (usually spastic), and, unless the brain damage is mild, may produce any degree of mental deficiency.

BI-SERIAL r—See CORRELATION (STATISTICS).

BLACK MOUNTAIN COLLEGE PLAN. Black Mountain College (Black Mountain, N. C.) emphasizes the importance of living and working in a community as a significant part of education. Real community living is hard: it involves tensions, compromises, responsibilities, and the discovery of common bases. But real experience in a community, as a framework to serious collegiate study, can be a source of profound self-knowledge, self-mastery, and genuine civic effectiveness.

Black Mountain College is kept small (a hundred and twenty) so that all relations remain personal; it is representative of modern life and is cosmopolitan. The students—both men and women—come from all parts of the United States, with a few from Europe. The

BLIND, EDUCATION OF THE

faculty are drawn from a number of European countries as well as America. The typical activities of a community are carried on in work, play, self-government, and community planning. In these each student plays an organic part, for he comes to have his unique place, as in any true community. The college is his home and his village during his years in it, and in this microcosm he is confronted with the major phenomena of human society.

Such a community life is perpetually educational. It forms the constant background to the central activity—study. It brings faculty and student members into a close, friendly relationship based on the sharing of responsibilities and problems. Together they have constructed a large modern study building. They work together cutting timber, operating a farm, or doing the office work of the college. A student is thus initiated into the discipline of labor, and perforce learns something of the way most of the American people have to make their living. He discovers how even routine work can become meaningful. He learns to use the basic tools, to handle simple machinery, and he gains some experience in administration and planning.

The union of learning with living emerges in community self-government. Problems affecting the entire community are discussed in general meetings, where all members are present and active. Here and in the meetings of the student body as such, students experience the difficulties and responsibilities of democracy. They are represented on almost all committees, with the exception of some that have a strictly academic function. Their chief officer is a member of the Board of Fellows, which administers the finances of the college and makes faculty appointments. They govern their own affairs, which on the whole are not felt to be apart from the affairs of the community.

Black Mountain is a college, not merely a community, and the center of life is study. High school graduation or its equivalent is required for entrance, and for graduation the standards of the better eastern colleges are maintained. The academic procedures are calculated to make learning a permanent habit and to help the student integrate the fields of study. The fine arts, languages and literature, the social studies, and the sciences are treated as of equal importance and the student is

expected to study in all fields during his first two years. To specialize in one field in preparation for graduation he must pass a comprehensive written and oral examination covering all fields, and demonstrate maturity as a person. For graduation he studies primarily in one field. Graduation is based on faculty review of a student's total accomplishment and upon the recommendation of an examiner from outside the college, who gives a comprehensive written and oral examination in the student's field of specialization.

The college is owned and administered by members of the faculty, entirely independent of outside control and endowment. This permits complete academic freedom. Classes usually take the form of small discussion groups, with intensive private tutorials for advanced students. The faculty-student ratio is about one to four.

Aesthetic and intellectual activity goes beyond the classroom. Students and faculty contribute weekly concerts of choral and instrumental music. There are periodic art exhibits and plays. Lectures on subjects of general interest are given by faculty members and guest lecturers, and regular radio programs are broadcast. In these creative activities and in the art classes flexibility and imaginativeness in meeting situations are developed.

Faculty members are chosen for the breadth of their knowledge and interests as well as for competence in their own fields, in the expectation that they will help the student integrate diverse knowledge through their own breadth of view. The faculty periodically discusses together the progress of each student and reviews the several comprehensive examinations, so that all members of the faculty are constantly aware of the work of all students.

Black Mountain College is perhaps unique in its fusion of higher learning with normal adult civic life and in its treatment of learning as a way of living. This gives an unusual possibility for the intellectual and personal integrations which the modern world needs so much.

K.K.

BLIND, EDUCATION OF THE. The problem of the education of the blind child or adult did not become a matter of social, religious, or professional concern until the latter part of the eighteenth century. It was

Valentin Haüy (1745-1822) who instituted the first systematic experiments in methods of educating the blind, and to him belongs the credit of being the first real teacher of this group. Haüy's *Essai sur l'Éducation des Aveugles* was the first basic textbook on methods in this field of instruction. The famous Vienna Institute for the Instruction of the blind was founded by Johann Wilhelm Klein in 1804. In our own century, the volume by Pierre Villey, *The Education of the Blind*, has provided a notable attempt to present teaching methods of value.

In the United States there were simultaneous efforts in establishing schools for the blind in New York, Boston, and Philadelphia. By 1940 there were 58 residential schools for the blind in the United States, eleven privately controlled, and 47 under some form of state control.

The movement for classes for the blind in the public schools began when Frank H. Hall secured the establishment of such a class in Chicago in 1900. Public school classes for the blind now exist in twenty-one cities.

Aims: The general aims in the education of the blind differ from aims for the sighted much less than is generally supposed; in the specialized and specific aims the divergence is more apparent.

The development of a strong and healthful physique is complicated in the case of the blind by special problems of physical conditions found among blind children; such as lowered physical resistance, lack of motor co-ordination, muscular apathy, poor posture, "tics", and other "blindisms."

The aim of providing a thorough elementary and high school education equivalent to that afforded seeing children is being mediated and individualized through guidance programs and curriculum offerings suited to different levels of ability and individual needs.

Special tools of learning receive greater emphasis in the case of the blind. These are, for example, braille reading and writing; the T-V-L, or Taylor, or cubarithm arithmetic slates; and special algebraic symbols, language signs, and chemical notations in braille. (See TOUCH READING.)

The general aim of providing vocational education with a view to self-support is broadening out into experimentation with new types of industrial, commercial, and trade training.

The socialization of each pupil to enable him to become an acceptable and efficient citizen of the community is an aim which is receiving direct attention in those specialized aspects in which the blind evince the greatest need.

The spiritual aims of education are especially urgent in the case of the blind, in the sense of inculcating a philosophy of life in which the meaning of their handicap can be understood and wholesome emotional attitudes developed toward the handicap, toward self, and toward society.

The education of the blind, as of the sighted, must prepare the individual child for successful living in the complex of socio-economic life of the changing world of our present age. The range of the curricula of such an educational program must include both academic subjects, and pre-vocational, vocational and trades courses. In a modern school for the blind all these must be planned for as fundamentals.

Procedures: The major point of view held in common by all teachers of the blind is that the blind child is first of all a normal child. Aside from his handicap he has a normal mental and physical structure. As a matter of fact, both the psychology of the blind,—if there is a special psychology,—and the methods of teaching the blind, differ from the psychology and methodology used in teaching the sighted much less than is generally believed by the public, and far less than professionals with their pseudo-scientific approaches and phraseologies would have us believe. Indeed, one reason for the lack of special treatises on methods of teaching the blind has been the absence of great differences existing between the normal methodology used in teaching the sighted and that used in teaching the blind.

Teachers of the blind have learned from years of experience that they are not dealing with children whose faculties are different from those of other children, nor are they teaching children whose other senses have gained them some measure of miraculous perception. Neither are the minds of these pupils extra-spacial. There is this difference, however: since one sense, vision, is lacking, the other senses must be developed to a higher degree in order to realize the goal of all teaching. This involves the resort to unique methods and techniques in order to accomplish

the ultimate aim of education of the blind child. The realization of the normalcy of the blind child is then the *sine qua non* of the expert teacher of this group of children.

Psychological problems: The degree to which a blind child develops a normalcy of living is directly dependent upon his success in substituting stimuli received through his unimpaired senses for those which are blocked off from him because of his sightlessness. To facilitate sensory substitution through widening sensory experience and to assist in the interpretation of that experience is the opportunity of teachers of the blind.

To teach and expect a blind child to do the same things that a non-handicapped child does is only human. It is his right to be encouraged to use to his advantage all the capacities he has without being retarded by being made aware of his limitations. It was a very fortunate blind man who, up to the age of six, did not know that he differed at all in physical perfection from his non-handicapped brothers and sisters. He learned to walk and run and play with confidence, absorbing the world about him through sensory stimuli which were available to him and interpreting it as his brothers and sisters did, unaware that there was a sensory realm which he could not enter.

In contrast to this ideal situation, the blind baby is sometimes kept a baby until four or five years of age. Some homes go so far as to keep a blind child in bed or tied to a chair. Fear, physical lethargy, lack of sensory experience, dulling of end-organs, and mental inactivity make a vicious circle resulting in retarded development. When once a child's innate urge to physical activity has been repressed and physical apathy sets in, his sense of touch is soon lost because of the poor innervation of his atrophied muscles, and all his movements become awkward.

Children enter school in all stages of this physical condition and resulting mental breakdown and it is often an arduous task to arouse interest and guide that interest into practical channels.

The essentials, then, are to refine the senses by exercise, to project these senses externally so that they are quick to glean all the information which they are capable of deriving, and by attentive application of earlier experiences to interpret the mental picture as it is recorded. Senses well trained in the scrutiny

of space will make it possible for the blind person to have conceptual notions of many objects and so have a well-equipped mind. The conceptions of many familiar objects, of animals, of plants, which a seeing person acquires by visual perception, are often attained by a blind person only after many years of effort. It is obvious that if a blind person's conceptions of things which form the basis of his action and reasoning are false or uncertain, his actions will be hesitating and his reasoning untrue. The education of a blind person must include not only the provision of correct mental equipment but also the examination and rectification of existing impressions. For freedom of activity a blind person must have activity patterns memorized by his hands and feet and ears as well as mental pictures of objects. All this equipment, developed and coordinated, enables the blind person to approach the goal of normalcy of manner; and all the special skills of trades or professions are incidental to this achievement.

C.R.A. and M.E.F.

BOARD OF EDUCATION. The board of education is the local educational authority created by legislative act and as such becomes the agency for the administration of the schools of the community. In practice, boards of education act in accordance with mandatory state laws and deliberate upon the provisions of permissive legislation. There are as many kinds of boards as there are types of school districts, there are boards for common school districts, town and township districts, county districts, and city districts, all differing somewhat in size, selection of members, organization, and function. This discussion is confined to a description of typical city boards of education.

Functions. The chief functions of boards of education may be classed as legislative, executive, and appraisal. As a legislative body, the board formulates and adopts broad policies for the conduct of education in the district; decides upon the amount of money to be raised locally (if the board is a fiscally independent one) and approves the annual budget; determines employment policies and makes contracts; and adopts rules and regulations for its own government as well as for the conduct of the schools of the community.

As an executive body, the board of education employs a professional specialist—the

superintendent of schools—to whom it delegates more or less completely the authority for the management and administration of the schools. Under the dual or multiple types of organization (See ADMINISTRATION, SCHOOL), there may be two or more persons, usually a secretary, business manager, or other officer, who share administrative responsibilities with the superintendent. The board itself may sometimes share in the executive function directly by delegation of certain matters to the board committees for execution. Such direct participation in executive matters is generally condemned by educational authorities.

As an appraising body, the board hears reports, is thoroughly informed on all matters of policy and administration, and evaluates its own activities and the acts of its agents.

Qualifications of board members. Legally there are few specified qualifications for membership on boards of education; the two most important ones are state and national citizenship and residence in the district. There is, however, general agreement concerning the qualifications of board members regardless of occupation, formal education, or sex. These qualifications usually center about the following: personal honesty, a background of experience to enable them to understand educational needs and resources, willingness to devote the time and energy necessary for rendering superior service, cooperativeness and community mindedness, sound judgment, and willingness to delegate to professional employees, without interference, the responsibility of administering the schools.²

Size of board and term of members. In the latter part of the nineteenth century it was not uncommon to find boards of education of thirty or more members selected to represent different parts of the district or wards of the city. Present day boards of education usually have from seven to eight members elected at large from the district or city. This tendency toward small boards is in harmony with the accepted educational theory which holds that small boards are better than large ones because more regular attendance can be secured and problems may more easily be considered by the whole board.

The most common length of term of school board members is four years, with provision for overlapping terms to insure con-

tinuity of policies. A recent study shows that the median term of office of board members in 214 cities of 30,000 population and over is four years. Eighteen of the cities had terms of office of only two years and one had a term of seven years.⁴

Organization of boards. The typical city board of education has at least three officers chosen from its members—president, clerk or secretary, and treasurer. For the conduct of their business, boards may be organized as a single unit or committee of the whole, or as a series of committees appointed for specific purposes. The single unit board is usually considered by school administrators as the more desirable type of organization, since under this plan all problems are given the consideration of the full board. This enables the board to function more as a legislative and policy making body which leaves the details of administration to a professional superintendent and his staff. Under the committee organization there are a number of committees of the board composed of one, two and three members. Committees may be organized for the purpose of considering problems on finance, instruction, personnel, plant, supplies. It is frequently urged that more attention may be given to the various phases of the school through the committee system since problems are first considered by the committee which makes recommendations to the full board for discussion and decision. The chief limitation of the committee plan is that board members are likely to assume administrative responsibilities which should be left to the professional specialist for study and investigation and presented to the entire board for decision.

Politics and boards of education. There is general agreement that boards of education should be removed as far as possible from partisan politics. The two most common means of insuring freedom from politics are to have members elected rather than appointed and to make them independent of municipal authorities.

It is common practice to have board members elected by popular vote in elections held at a time other than the time of municipal, local, state, and national elections. Although in some states board members are elected in the general elections, they are frequently placed on non-partisan ballots. The appointment of board members is less desirable than

election because of the political nature of those who appoint them.

Another means of insuring freedom from political interference is through statutory provisions making them fiscally independent of the municipality or other state or local agencies. Studies show that school systems with fiscally independent boards are slightly superior to those with fiscally dependent boards.

Relation to superintendent, school, and community. The board of education is generally regarded as the policy making body, whereas the superintendent is the executive officer of the board employed to administer the schools. In some states the superintendent has duties and responsibilities imposed upon him by state law or regulations that are quite independent of board action. He is therefore considered both as an employee of the board and as a state school official. (See SUPERINTENDENT OF SCHOOLS.)

Although the board of education is the local governing body of the schools of the city, the best educational thought would not permit the board itself to administer them, but would require that it entrust this responsibility to its employed educational specialist and his staff. The board's functions with respect to the schools are more largely legislative and evaluative than administrative or executive.

In its relation to the community, the board of education is the agency which represents the people of the community. Although boards are given their authority by legislative enactment, they cannot act independently of the will of their constituents, but are under obligation to represent their communities. (See also BOARD OF EDUCATION, LOCAL; BOARD OF EDUCATION, STATE; BOARD OF EDUCATION, TOWNSHIP.)

BOARD OF EDUCATION, LOCAL.

The term *local board of education* is used when the agency having authority deals directly with the pupils, teachers and parents, in the basic administrative unit, and when there is no intermediate agency between the board and the constituents to be served. A local board of education may be a city board, a district board, or a county board, depending upon the basic unit. District and township boards are frequently known as boards of trustees or boards of school directors or township trustees. The discussion here is centered about the local boards of common school districts.

The most numerous type of school district in the United States is the common school district of which there were approximately 109,000 in 1933.¹ These represent chiefly the rural one-and-two-room ungraded schools and graded schools in towns and villages. They are the typical school districts in twenty-six states. The boards of education or local school trustees of the common school districts are usually made up of three members elected by the people of the district at the annual meeting. The organization of the board is simple; usually there are three officers chosen by the board—president, secretary or clerk, and treasurer. They exercise general control over the schools in all matters except those entrusted to the electors of the district in annual meeting assembled. In some states the amount of local tax money to be raised is determined not by the board but by the annual meeting.

Local boards of education that do not employ a superintendent and delegate the executive functions to him must themselves assume executive authority. This is true in most common school districts in rural areas. The local board of education has the usual corporate powers of other school districts and is the lawful agent of the district. It may buy and sell property, make contracts, sue and be sued, and carry on all functions related to the maintenance of the schools. (See also BOARD OF EDUCATION.)

BOARD OF EDUCATION, STATE.

The most important agency of state wide jurisdiction to which educational authority has been assigned by statute is the state board of education. The term, state board of education, is extremely difficult to define since there are usually several boards or commissions which exercise some educational functions. Chambers has shown that the state of North Dakota has two such boards, whereas the state of Pennsylvania has eighteen.¹

Commonly there is one state board which has more authority over elementary and secondary schools than the others and may be designated as the state board of education. Forty states have such boards.

Functions. In all the forty states having state boards of education these boards have general jurisdiction over elementary and secondary education; in eighteen states the board has jurisdiction over teachers colleges and normal schools; in nine states they also control state colleges and other teacher education institutions; while in four states the state board has control of the state university. The specific educational functions relative to elementary and secondary schools vary greatly in the different states depending upon the degree of centralization. Such functions as the certification of teachers, inspection of schools, supervision of vocational subjects, distribution of school funds, are frequently assigned to state boards.

Selection and composition. The most common method of selecting state board members is appointment by the governor. This method is employed in twenty-six states. In four states the majority of board members are elected by popular vote; in one state they are appointed by the legislature and in one state they are appointed by the chief state school officer. In eight states boards are composed wholly or largely of ex-officio members.²

Ex-officio board membership has been called into question because the members are chosen for other elective or appointive offices, which do not necessarily qualify them to

serve as members of state boards of education. The method of electing board members by popular vote has been opposed because many well qualified persons often refuse to have their names placed on general election ballots. Although the method of appointment by the governor is not always satisfactory it seems, on the whole, to be the most desirable one for the selection of members of state boards of education.

Size and term of office. The size of state boards of education ranges from three to twelve. The most frequent number is seven.² The term of office of board members is four or more years in thirty-five states with overlapping terms to insure continuity of policy. Board members usually serve without compensation although they are paid necessary expenses. (See also BOARD OF EDUCATION; STATE DEPARTMENT OF EDUCATION; STATE SYSTEMS OF EDUCATION.) W.C.R.

BOARD OF EDUCATION, TOWNSHIP. The township is the basic unit of school administration in three states—Indiana, New Jersey and Pennsylvania. The township school unit embraces the territory of the civil township, exclusive of the area in the independent districts, cities, boroughs or other exempted districts. Description of the township board of education is difficult because of the different forms of such boards in the three states; a statement of township boards in each state shows the chief differences.

In Indiana the schools of the township are under the control of the township trustee who is elected by the people for a term of four years. According to law, he has practically complete charge of the schools of the township; in practice, however, he is assisted by the county superintendent. The trustees of

the county elect the county superintendent who has general supervision of the rural schools.

In New Jersey the township organization is one of the types of school organizations included under the provisions for Article VII, districts which are governed by a board of education of nine (or a reduced number) members elected by the people. The township board of education functions much like boards in incorporated towns and boroughs under the same legal provisions.

In Pennsylvania, all school districts including city, incorporated town, or township are classed as school districts of the first, second, third, and fourth class, depending upon their population. Township units are governed by board of directors, elected or appointed and varying in size depending upon the class of district in which they serve. The board of directors is empowered to establish schools, to provide equipment, to tax the township for school support, to make rules and regulations for the government of the schools, and to carry on other functions necessary to the maintenance of efficient schools. BOLIVIA, EDUCATION IN. Bolivia has essentially the same cultural background as Peru (*q.v.*) and Ecuador (*q.v.*). With them it once formed the Inca empire. Only little more than 10% of 3,500,000 population is white, about 80% is Indian or *mestizo*; the majority of the people still speak the native languages: *Quechua*, and, in the South, *Aymará*. They are extremely destitute, suffering as well from the high altitude where most of them live, as from economic misery. Bolivia, though, is very rich in minerals, particularly tin. But the perpetual fights between groups of army officers for political power and the many unsuccessful Indian revolts have to this moment prevented

the nationwide exploitation of these riches. The defeats in the war of the Atlantic (1879-83) and in the Chaco War (1932-35) still further increased the difficulties. The first made the country landlocked, the second proved its weakness, which invites the European dictatorships as well as the more powerful neighbors to lay their hands on Bolivia's riches. Under these circumstances few educational facilities could develop. Of the little that is claimed in contradictory statistics, nobody can say what really exists and how much the terms university, secondary, vocational, and elementary school really mean.

The Spanish conquest gave educational authority to the Church. Of the three universities the old one of Chuquisaca was founded in 1624, and the others under the first dictator, Santa Cruz, in La Paz 1830 and in Cochabamba 1832. Following French ideas, the liberator Sucre established as early as 1825 an elementary public school system and some secondary schools. In 1912, under the influence of a Belgian adviser, Mr. Rouma, the attempt was made to weaken the authority of the Catholic Church by forbidding religious instruction in the public schools. On the whole, 2,000 elementary schools with 145,000 students, 27 secondary schools with 5,522 students, and some normal and vocational schools are said to be in operation. With the accession, in turn, of Presidents Toro and Busch, both of national and socialist convictions, and of Peñaranda, a full-blooded Indian himself, greater attention was being paid to the Indian problem. The first normal school for teachers of native schools was opened in 1931, and, by 1942, 16 centers of Indian education were claimed. The agreement on the export of all tin and tungsten to the United States during World War II led to an improving economy and a hope that this trend would become stronger and finally result in a reform, perhaps on the Mexican model. BOOKKEEPING AND ACCOUNTANCY EDUCATION. The teaching of bookkeeping, usually on a single entry basis, began in the United States in colonial times, when it was carried on not infrequently in colonial night schools. In the first quarter of the nineteenth century the subject became increasingly important in private business schools in the larger cities along the Eastern Seaboard. As businessmen became more reluctant to give time to the training of apprentices, and as young workers grew impatient to achieve speedy occupational competence, the opportunities for formal school instruction in bookkeeping became more evident. Bookkeeping instruction attained a level of considerable efficiency in the Civil War and post-Civil War period.

The development of gigantic corporate enterprise in the United States made accountancy a necessary instrument in business control. At the beginning of the twentieth century, therefore, several universities established collegiate schools of business. Accountancy, was, and continues to be, the core subject material of most business schools at the college level. The establishment of accountancy as a profession, and the formal grant by the several states of certification as "Public Accountant," have made training in this area a vocational objective of many college students. It now ranks as one of the outstanding courses in occupational training of American universities, while supplementary training in accounting, as an aid to business management and improved understanding of economic theory, is also growing in popularity.

Even before the twentieth century the teaching of bookkeeping was included in some secondary schools. At that time most of the teachers and subject material were taken for this purpose from the private business schools, but as time went on there was a gradual adaptation of materials to the needs of secondary schools. The journal approach, developed in the private business school, has been supplanted quite generally by the balance sheet approach. In other words, the formal logical sequential presentation of subject matter has given way to an emphasis

upon understanding and interpretation, rather than upon the mere ability to perform routine operations. The increasing difficulty which high school students experience in obtaining initial positions as bookkeepers has caused a reconsideration of the place of bookkeeping in the secondary school, resulting in a decrease in the amount of formal paperwork and in an attempt to enrich the interpretive aspect of bookkeeping. Because of a growing tendency to question the value of a formal knowledge of opening and closing entries and of the ability to work out elaborate work sheets, there have been developed courses in socialized bookkeeping and record keeping designed to appeal to the heterogeneous student body of the secondary school. BOOKSTORE, SCHOOL. Many schools find it advisable to set aside one room in the building as a depository for textbooks and other school supplies. This room, known as the bookstore, is operated under the direction of the administration.

With the consent of the board of education a school store may be opened, through which textbooks and school supplies are retailed to pupils at a small profit.

The principal advantage in the school's operating its own store is that it makes possible a saving to the parents and insures the maintenance of standards of quality throughout all the classrooms of the school.

The principal disadvantage in the school's operating its own bookstore is that it places an added responsibility on the administration. Therefore, if satisfactory service can be secured from community stores, it is usually considered better to rely upon them for handling the books and supplies. O.G.J.

BRAZIL, EDUCATION IN. **Organization.** Brazil is a federal state. The central

government establishes the foundations and general policies of education throughout the country. The states organize and maintain their own educational systems. The federal administration of education is conducted primarily by the *Ministry of Education and Health*. There are, however, certain educational services placed under the control of other ministries. Each state maintains its own department of education. The municipalities also may maintain schools, which are, however, directly inspected by the respective state department of education. Nearly half of the total number of schools in the country are maintained by the states; the municipalities support about one-third of the schools; private agencies finance and are responsible for about one-fourth of them. The Federal Government maintains only standard institutions, comprising higher, secondary, and industrial schools.

Elementary education is provided, in general, through courses having five grades. Secondary education comprises two successive divisions: the gymnasium (four years) and the college (three years). The curriculum of the gymnasium is uniform for all students, who, after graduation, may enter any industrial, commercial, or normal school. The college has two different sections: classical and scientific. Higher education offers courses in philosophy, law, medicine, pharmacy, dentistry, education, economics, engineering, agriculture, architecture, fine arts, music, and physical education, all according to uniform standards. Industrial education is provided in industrial schools (four years) for skilled workers, and in technical schools (three years) for managerial positions. The training of elementary school teachers is conducted in normal schools maintained by the States; that of secondary school teachers is undertaken in schools of philosophy, in which there are departments of education.

Significant educational movements and leaders. The *Jesuits* were the early educators of the country in colonial days. The migration of the Royal Portuguese Family to Rio de Janeiro in 1808 was responsible for the creation of a few schools of higher learning. The Independence, proclaimed in 1822, did not create, however, a greater interest in education. Social life was governed by an agrarian economy, based on vast rural

properties, and by slavery. This situation explained a particular trend toward a very literary and excessively formal culture. At the close of the Empire there were, despite projects of remedial legislation and the efforts of prominent statesmen (João Alfredo, Leônicio de Carvalho, Rodolfo Dantas, Rui Barbosa), but 14 children per one thousand inhabitants enrolled in the schools. After the abolition of slavery (1888), changes in the type of economy began to take place, leading toward the industrialization of the country. Through the influence of Benjamin Constant Botelho de Magalhães, one of the founders of the Republic, a Ministry of Public Instruction was created in 1890. But it did not last very long. Up to 1930 the Central Government did not show much interest in education; it did, however, create a number of vocational schools and subsidize elementary education in the Southern States where there were numbers of colonists of foreign stock. In 1930, Brazil had 51 pupils per one thousand inhabitants. During this period, certain states showed a considerable development of their educational systems. Such development along with the spread of modern educational ideals, was very irregular in the various regions of the country. In the Empire, public education was dominated by formal instruction and the practice of the Lancastrian system. Later on, the theories of Herbart were accepted, and, more recently, those of progressive education, which is known as the *escola nova* movement. It is interesting to observe that the ideas of reform were almost always adopted through governmental initiative before they were sufficiently known and practiced by educators. The first movement deserving special emphasis is the reform of public instruction of the State of São Paulo, undertaken in 1894, by Gaetano de Campos, Gabriel Prestes, and Cesario Mota, and consolidated afterwards by Oscar Thompson in 1911 and A. Sampaio Doria in 1920. Several states and the Federal District adopted important measures for the reorganization of their school systems (Distrito Federal, 1918, Afrânio Peixoto; Ceará, 1922, Lourenço Filho; Bahia, 1925, Ansio Teixeira; Minas Gerais, 1927, Francisco Campos; Distrito Federal, 1928, Fernando Azevedo; Pernambuco, 1929, Antonio Carneiro Leão). The movement of political reorganization,

expressed in the national revolution of 1930, was reflected in the field of education, giving emphasis to many ideas of reform. In the coordination of these new ideas, the *Brazilian Education Association* has exercised a prominent role since its foundation in 1924 by Heitor Lyra da Silva and other educators. This association promotes forums, courses, publications, and national congresses of education. The Provisional Government (1930) created the *Ministry of Education and Health*, and emphasized the trend toward greater centralization of educational administration. Higher education and secondary education were reorganized in 1931. Elementary education expanded, doubling the number of schools and pupils. The ideas of reform according to the principles of progressive education showed a great development throughout the country. In 1933, a group of modern educators published a manifesto *Educational Reconstruction of Brazil*. This document analyzed the cultural situation of the country and studied the importance of a complete system of education having an organic structure according to the necessities of Brazil and the modern economic and social trends of the present civilization. The organization of national agencies devoted to statistics and the creation of a technical organ under the Ministry of Education are contributing toward a new objective in education. In 1938 the Federal Government created the *National Institute for the Study of Education*. Many books were written, interpreting new theories, spreading information, and reporting results of educational researches. A number of these books have been translated into Spanish, thus circulating in the other Latin American republic. Expressions like *active teaching*, *project method*, *pupil self-government* and others became current. Recent federal legislation (1942) such as the laws of industrial and secondary education, expresses the objectives and techniques of progressive education, stressed by Minister Gustavo Capabema in his introduction to the laws.

Educational Relations with the United States. During the early days of Brazil, the ideas concerning education were exclusively those of Portugal, but these were soon powerfully and continuously influenced by French theories. Italian and German influences were present in certain states that had received a

more intense flow of immigrants. Since 1870, however, there has been an ever-increasing influence of American educational ideas, at first through the influence of schools and colleges founded by missionaries. The influence of new educational methods introduced by the *Escola Americana* (São Paulo), was great in the reform undertaken by this State in 1894, in which an American teacher, Miss Marcia Brown, cooperated. Agricultural education was improved in 1921, in Minas Gerais, by an American specialist, Dr. P. H. Rolfs. Medical education received the co-operation of Dr. Bowman Crowell, in the *Instituto de Manguinhos*; of Miss Eton Parsons, in the Nursing School *Ana Nery* at Rio de Janeiro; and of the Rockefeller Foundation, which helped in the erection of buildings for the *Faculdade de Medicina de São Paulo*. This foundation grants fellowships to Brazilian physicians for graduate study in the United States. In 1929 the Carnegie endowment offered ten fellowships to Brazilian teachers. In the following year summer courses for American students were conducted in Rio de Janeiro, with the collaboration of the *Institute of International Education*, New York. In 1939, the University of Pennsylvania conducted a summer course in Rio de Janeiro. An increasing number of Brazilian students are receiving scholarships for study in the United States, through the *Instituto Brazil-Estados Unidos*, created in 1939 as a central private agency fostering cultural relations between the United States and Brazil. English is a compulsory subject for all secondary students.

Statistics. There are four universities in Brazil: *Universidade do Brazil*, in Rio de Janeiro; *Universidade de Minas Gerais*, in Belo Horizonte; *Universidade de São Paulo*, in São Paulo; and *Universidade de Porto Alegre*, in Porto Alegre. The extent of education in Brazil may be seen from the following:

	Schools	Teachers	Students
Elementary education	42,794	82,907	3,350,737
Secondary education	886	12,733	183,896

BROAD-FIELDS CURRICULUM. A curriculum composed of a few required large areas or major trunk lines in which the basic subject matter is drawn from the total area without regard for subject lines. It is a new method of selecting and organizing the essential subject matter within the area. Some common examples in the elementary and secondary schools are social studies, science studies, language arts, general arts. In the junior and senior colleges the broad-fields curriculum is composed of a series of required survey courses the most frequent of which are the physical sciences, the biological sciences, humanities, fine arts, home living, philosophy, and religion. Sometimes the areas may be described as immediate social relationships: work, leisure, personal living.

The broad-fields curriculum developed as a protest against the freedom of the elective system in the colleges and the activity program in the elementary schools, each of which was also a protest against the fragmentation of the traditional subject curriculum. Advocates claimed it was a much needed system which avoided some of the major pitfalls of the extreme subject organization and also the lack of planning which seemed to accompany

the freedom under the elective and activity programs. These antecedents have resulted in two rather different types of practices. The dominant group leans heavily toward the subject viewpoint, structure, and practice. The minority group accepts the general framework, but tries to keep alive within it the previously accepted principles of pupil-teacher freedom. More recently the movement toward the broad-fields curriculum has been supported by the advocates of general education who oppose the narrow specialization which the subject curriculum demands.

The fundamental educational conceptions underlying the broad-fields curriculum are the same as those underlying the subject curriculum. The basic idea is that of a curriculum planned in advance by older persons for less mature persons to study. The emphasis is upon teaching, in as psychologically valid a manner as possible, certain organized bodies of knowledge within the accepted area. Differences in designation of fields arise out of the approach. Moving from the subject viewpoint to broad-fields, the subject designation, such as social studies, is most frequently used. Beginning with an analysis of the larger needs of adults, the result is usually social living, home living, work, leisure, or some other more general grouping.

The broad-fields curriculum is receiving widespread study at the moment. To many it is a first step in the improvement of the subject curriculum, for it breaks from the scientific study of subjects which is valuable to only a few potential specialists. Its chief merit lies in the larger area from which the basic material is drawn. In planning a curriculum existing knowledge must be re-evaluated in the light of new needs. Its chief defect is that it does not go far enough to challenge the framework within which such thinking takes place. Unless this framework can be modified, little permanent progress in curriculum making can be achieved. (See CURRICULUM.)

BUILDINGS, SCHOOL. Standards. Evaluation of school buildings is based upon the recognition of certain standards of efficiency in facilitating instruction and in meeting the needs of the community. These standards usually reflect the ideals of authorities in the field of education and school architecture at any particular period. School building standards change with changes in educational philosophy and new conceptions of educational psychology.

Score cards for one-room rural school buildings, for elementary school buildings of larger school systems, and for high school buildings have been devised to facilitate evaluation in terms of certain recognized standards. An advantage of the score card is that it fixes attention upon the details of the building and enables comparison of all or any part of the school plant with recognized standards for that particular type of building. A typical score card is divided into a number of major divisions, such as: I. Site, II. Buildings, III. Service systems, IV. Classrooms or recitation rooms, V. Special rooms. Each of these major divisions is also divided into a number of subdivisions such as (under "I. Site") A. Location; B. Nature and condition; and C. Size and form. These subdivisions are in turn divided into the number of topics necessary to cover the major standards included in the evaluation, such as (under "A. Location") 1. Accessibility; 2. Environment.

In the construction of the score card a certain number of points is allotted for the ideal building as measured by the standards—usually 1,000 points. These points are distributed among the major divisions according to the opinion of the author of the score card as to the relative contribution of each division to the total efficiency of the plant. For example, one score card for high school buildings, based upon 1,000 points for the ideal building, awards 100 points to "Site," 155

points to "Building," and 270 points to "Service systems." The remaining 475 points are distributed among the other four major divisions of the score card. The points allotted to the major divisions are likewise distributed among the several subdivisions and redistributed among the several lesser subdivisions or items. The score on any subdivision is based upon the conditions found as compared with these standards. The total score is the sum of the scores on all the individual items. The score card contains directions for interpreting the scores obtained.

The standards upon which a score card is built are usually published in a separate bulletin to be used in conjunction with the score card. These standards are arranged in outline form according to the major divisions, subdivisions, and items appearing on the score card. The score card should be used only in connection with the outline of standards used in its development.

Most states and local governmental units prescribe for school buildings certain minimum standards with respect to safety, sanitation, and general character of construction. These standards incorporated in the school laws and municipal ordinances are intended to protect the school children and the occupants of adjacent property from injury resulting from faulty construction, careless habits, or fire. Regulations are enforced through inspection at intervals by authorized persons.

With respect to fire hazards these regulations usually are concerned with fire-resistive construction materials, such as brick or reinforced concrete, fireproof stairways and corridors, adequate numbers of exits, handrails on stairways, doors opening outward with panic bolts and catches to hold doors open, fireproof roofing, fireproof boiler rooms, adequate provision for fire hose and fire extinguishers, protection for electric wiring and outlets, and safe disposal of waste materials.

With respect to safety and sanitation of school buildings, state and local governments also set up minimum standards for such details as strength of walls, carrying load of floors, strength of foundation, sewage disposal, proper heating and ventilation facilities, adequate lighting, and sanitary water supplies and toilet systems.

Each of the forty-eight states has statutes providing authority and prescribing limitations under which school districts and school officers may or must proceed in planning or constructing school buildings. The extent of direct state control varies with the several states. Some provisions are mandatory for boards of education, while others are permissive, depending upon the degree to which boards have been delegated authority to act upon their own discretion. These provisions for the control of school buildings include selection of school sites, issuance of bonds, legal debt limitations, contracting with architects and builders, advertising for bids, payments for work, protective bonds, liability for fire, theft and other damage during construction, approval of plans by some state agency, management and disposal of school property, etc.

Utilization of School Buildings. Studies in the use of school buildings reveal great waste. It is out of the ordinary to find a building that has all of its rooms in use every period of the school day. Rarely are all the schoolrooms of a building utilized to their fullest capacity. Some waste in utilization of the school plant inevitably results from the short school term and the six-hour school day. Few schools are in session for more than ten months and some schools operate for only six or seven months.

Moreover, a great deal of waste results from failure to use the plant to its full capacity during the school day. One study found "the average percentage of *room utilization* in 58 schools to be only 75.4, and the average percentage of *pupil-station utilization* to be only 41.1."⁵ The loss from failure to use the school plant to its maximum capacity during the school day becomes more impressive when one considers the tremendous investment in the school plants of the United States (estimated at eight billion dollars in 1941). Much of this loss results from lack of foresight in planning the buildings, from failure to adjust the school organization to meet the needs of the school program, and from lack of care in the scheduling of classes and the assignment of rooms.

Often careful survey of the school building to determine the extent of utilization will reveal that what seems to be an overcrowded condition is merely improper utilization of

the plant. A familiar technique for such a survey is the construction of a chart which shows the use of each room during each period of the day for each day of the week, the pupil capacity of the room, and the number of pupils using the room each period. This chart shows at a glance the extent of room utilization and of pupil capacity utilization.

Most building surveys show that such rooms as the auditorium, the gymnasium, the cafeteria, and shops and laboratories are used least. There is a tendency today to make provision for greater use of these special rooms as teaching units and for community purposes. Auditoriums, gymnasiums, and school libraries are being located on first floors and constructed so as to serve both school and community needs. Doors are provided which may be opened to the public without opening the rest of the building. The increasing tendency to use the local school building as a meeting place for community activities reduces the loss from lack of utilization.

Cost. School buildings today range in cost from less than one thousand dollars to several million dollars. A single classroom in a modern school building may cost more than fifteen thousand dollars. The plan of the building, the materials of construction, and the workmanship are important factors in determining the cost. For example, studies show that a small one-story structure of the "open type" plan costs more per cubic foot than a large two-story square building. There are many factors which influence the cost of school buildings, such as kind and availability of materials used, climactic and physical conditions, architectural fees, prices for materials and labor, the style and structure of roof, interior finish, plumbing and electric service, and foundations.

No single measure for determining the relative cost of school buildings has been universally accepted. Cost per cubic foot is probably the most common unit of measure. Other units of measure include cost per room, cost per square foot per pupil accommodated, cost per square foot of educational floor area, and cost per weighted pupil station (the pupil stations determined through the use of floor area standards are weighted according to the different cubatures for the various types

of pupil stations such as classroom, auditorium, and library).⁶ Unit measures of cost are probably of most value when used to compare buildings within communities similar in climatic, physical, and economic conditions. It should be remembered that a building may have a low cost per cubic foot and yet in reality be expensive if a relatively small percentage of its volume is available for use.

Equipment. The problems of equipment for school buildings are so closely associated with the educational plan and the curriculum offered that it is difficult to think of one except in terms of the other. The study of equipment problems constitutes an important preliminary step in the planning of a school building.

The plan for school equipment, like the plan for the school building, should be developed cooperatively. There is an increasing tendency to enlist the services of entire staffs of all departments in the planning of the equipment which they are to use. Much of the progress made in recent years in adapting school equipment to educational purposes has been brought about through cooperative planning.

The plan for equipment for a school building should accompany the specifications for the building, so that the architect may understand clearly the use to be made of each unit of the building. The plan for equipment should indicate specifically the type and location of each item of equipment for each unit of the school building.

The modern classroom must provide for both individual freedom and group activity. Greater adaptability is possible if most equipment is movable. Desks, tables, chairs, bookcases, and map stands are examples of movable equipment.

The tendency in elementary schools is toward tables and chairs for kindergarten and first and second grades, and a combination of tables and chairs and movable desks for the upper elementary grades. Much of the equipment needed in the school can be made or acquired at little or no cost. Old carpenters' tables may be cut down to provide space for painting supplies, for lunch equipment, and for rest pads. Tables for clay modeling and for science work can be made from shipping boxes. Easels and bulletin boards can

be constructed by the children from scrap lumber. They may also help construct many kinds of playground equipment. Children delight in making things and acquire many desirable learnings from such activities.

The Committee on Schoolhouse Planning and Construction of the National Education Association lists these factors to be considered in planning school buildings:

1. *Adaptation to educational needs.* The plan should conform to the schedule of rooms already adopted.

2. *Safety.* The corridors and stairways should permit the building to be vacated in three minutes even if one stairway is made useless by smoke. . . .

3. *Healthfulness.* Every room should have abundant natural light. . . . The toilets should be distributed conveniently on each floor and should have windows opening directly to the open air. . . . There should be a sufficient number of bubblers for drinking purposes, so located that they will not block traffic. . . . Washbowls should be adequate in number. . . . To avoid damp, unsanitary, or poorly ventilated rooms there should be no basement as this term is usually understood, with the possible exception of space for the heating plant. This plant should, when possible, be located entirely without the confines of the building. In rural communities the one-story type of building is often desirable, as it is a reasonable guarantee of safety in case of fire. To avoid excessive climbing of stairs the building should not contain more than three stories and a basement, except in congested cities where land is very expensive. . . .

4. *Convenience.* The location of rooms with reference to one another should be carefully studied. . . .

5. *Expansiveness.* The building should be so planned that it can be enlarged as much as may be needed without unnecessary cost and without cutting off natural light and ventilation of any of the existing rooms. . . .

6. *Flexibility.* Since it is not possible to foresee all the requirements of the future, every school building should be so planned and constructed that changes can be made if necessary in the lengths of the rooms. . . .

7. *Aesthetic fitness.* The skill of the architect as a designer is shown by his ability to clothe the building with a pleasing exterior without doing violence to the interior. The

exterior elevation should reflect the major functions of the school itself. It should give evidence of the fact that the building is a pleasant and attractive place in which young people are happily and busily engaged in worth-while enterprises. . . . The interior should likewise produce attractive and pleasing effects. The decorations should be modest and cheerful. The finish must be such as to lead the pupils to take pride in keeping the building free from injury and all disfiguration.

8. *Economy.* Economy in the plan is secured by:

(a) Accurate determination of the size needed for each room. This depends in turn upon the adoption of scientifically studied layouts. . . .

(b) Duplicate uses of rooms.

(c) Elimination of waste areas. The percentage of floor area devoted to "instruction" (which includes not only classrooms, laboratories, and shops but also the auditorium, gymnasium, and library and their accessories and study halls, also lunch rooms if used as study halls) should not be less than 50 per cent of the total floor area, and may, under favorable conditions and careful planning, reach 60 per cent or even more.

(Page 1 of the report recommends that the several parts of the building should utilize approximately the following percentages of space: walls and partitions, not over 10 per cent; flues, not over 3 per cent; stairs and corridors, not over 20 per cent; accessories, not over 1 per cent; administration, not over 16 per cent and instruction, not less than 50 per cent.)

BULLETIN BOARD. A rectangular board of convenient size, made of cork or of soft composition material and placed on a corridor, classroom, or office wall. To it may be fastened papers or cardboard materials containing announcements, records, schedules, illustrations, news items, or anything of interest to members and patrons of the school. In the classroom this board is usually as wide as the blackboard and is placed at one end of the room. Objects and materials are sometimes put on the bulletin board for exhibit purposes, but the board is not used primarily for display purposes.

There are many other uses to which the bulletin board may be put. For example, by posting clippings from newspapers and magazines the teacher may invite students' attention to current developments relating to activities in which the class is engaging. When the class knows that it is the students' rather than the teachers' bulletin board, the bulletin board may serve many of the purposes of a class newspaper.

BUSINESS ADMINISTRATION OF SCHOOLS. *Business administration of schools* refers to the planning and management of all activities of the school corporation having to do with the raising or spending of money for the promotion of the educational program. The financial and educational aspects of school administration are so interdependent that one person must direct both if the schools are to operate at maximum economy and efficiency. Yet the business administration has been and still is separated from the educational administration in some school systems. This separation of powers is called the *dual system*. Under it the superintendent of schools does not control the business direction of the schools, although his having such control is considered to be essential by students of educational administration.

The trend has been toward unity of control under a superintendent qualified to direct business activities toward the best educational results.

The activities considered to fall under business administration are numerous and the terms used to designate them are varied and not always descriptive. In *Problems in Educational Administration* by Strayer, Engelhardt, and others five main types of activities are listed:

(1) those primarily secretarial (having custody of records of the Board, including seal, contracts, securities, title papers, insurance policies, receipts, bills, etc.; making reports; keeping records; etc.);

(2) those primarily financial (preparing annual budget; preparing, examining, and certifying pay rolls; insuring school property; collecting and disbursing school funds; etc.);

(3) those pertaining to the purchasing of supplies (listing needed supplies, advertising bids, keeping perpetual inventory, etc.);

(4) those pertaining to the operation and maintenance of the physical plant (inspecting of school plant and equipment, preparing specifications, certifying bills for maintenance, etc.); and,

(5) those pertaining primarily to capital outlay (acquiring title to property, supervising voting and issuing of bonds, approving plans and specifications of architects, etc.).

Business administration is good only when it keeps in full focus the primary functions of the schools. It can be said, therefore, that the best test of efficiency of business administration is the effectiveness of the schools. The most important of business activities from this point of view is the preparation and administration of the school budget, which is a work plan for a fiscal period setting forth the educational program, the expenditures involved, and the sources of the revenue needed. When the budget is approved by the board of education it becomes the responsibility of business administration to convert the plan into educational results with a minimum of changes and a maximum of smoothness. (See FINANCE, SCHOOL.)

BUSINESS ARITHMETIC. Place in the Curriculum. The practical value of mathematics, particularly arithmetic, in the management of business has been recognized since the colonial period. Arithmetic was originally introduced into the curriculum because of its value in business. Since that time commercial arithmetic has remained as the most important vocational branch of elementary mathematics. Transactions among business units, as well as interior control of each unit, are continually giving rise to problems that require mathematical treatment. Thus, any person entering business, whether as executive or clerical worker, requires a detailed understanding of the business uses of mathematics.

The purposes for which courses in business arithmetic are organized appear to fall under two general headings—computational and informational. The computational aims include skill and accuracy in the operations, including percentage; the proper usage of business calculations; and the use of graphs and other means of presenting quantitative data. The informational aims are based on the fact that mathematics affords an effective means of studying the nature, organization, and conduct of business. The business calculations provide the means for understanding the activities of the business units, the transactions that give rise to the calculations, and the duties of those who make the calculations in the real situation.

The National Survey of Secondary Education found that the course in business arithmetic is offered as an elective in either the ninth or the tenth grade with about equal frequency (3).

Trends in Content. Trends in the content of business arithmetic courses are mainly directed to the need to make the courses functional, and to changes in the business usages of mathematics. Complaints of employers have tended to focus attention on the functional purposes of the course, and there has been little tendency to stress disciplinary aims. As a result, studies of business usage of mathematics have led to the discarding of obsolete processes and compli-

cated operations, and to the introduction of the calculations most often used. Modern textbooks and courses of study reflect the increased use in business of graphs, simple statistical procedures, and the calculations necessitated by taxation and social security legislation.

Trends in Classroom Procedures.

There has never been a clearcut policy in the schools as to which department is responsible for business arithmetic. Some administrations assign it to the commercial instructors, others to the mathematics instructors. There are, of course, advantages and disadvantages to both plans, but the net result has been the lack of a discernible trend in classroom practices based on a developing theory of learning. Such tendencies as exist are designed to increase the value of the subject for guidance purposes. To this end classes are reported observing business activities, setting up business situations in the classroom, and making surveys of community problems. There are few reports, however, of the use of diagnostic and remedial practices in correcting difficulties with the fundamental operations, or a scientific treatment of such topics as problem solving. (See ARITHMETIC, TEACHING OF.)

BUSINESS EDUCATION. Business education is one of the most important areas of subject matter in the secondary school in terms of enrollment, being exceeded in the average school only by English. While book-keeping was a required subject in the English High School established in Boston in 1823, business subjects were not general in high school until the beginning of this century.

Since then these subjects have had a phenomenal growth. Part of this was due to the many opportunities available to high school graduates in clerical positions, and part was due to the need for subject matter better fitted for the ever increasing secondary school population. The academic subjects are poorly fitted to meet the needs and interests of the mass of children now going to secondary schools, and since until recently, and to a considerable extent even at present, business subjects were the only alternatives, pupils flocked to business subjects, sometimes as the lesser of two evils, but more often with the hope of securing business positions from their training.

The enrollment in business education courses is considered by some to be greater than can satisfactorily be absorbed by industry and business. Even shorthand has been bitterly attacked though it remains the best specific training likely to serve as a basis for job placement for most young women. To meet these criticisms there has been a greater emphasis upon such subjects as junior business training, economic geography, business law, economics, and similar social-business subjects. Attempts are being made to integrate these subjects into a well organized subject matter sequence, and, with considerable success, to broaden the job opportunities in line with the increasing diversity of clerical positions that have developed. This is part of the explanation for the growth of office practice as a specific business subject. Distributive education also has been heralded as a field better fitted to meet the needs of more students.

The upgrading of the age of beginning employment in business has resulted in a demand that specific job training for business be largely relegated to the junior college level and that the secondary school limit itself, with the possible exception of the twelfth year, to general pre-vocational business education. Thus far this demand has not been realized in practice.

The private business school which was the original institution giving business education has been holding its own with difficulty. Nevertheless those private business schools which have kept themselves up to modern business standards and which have dealt with mature post-high school students have con-

tinued to render a useful service.

The collegiate school of business was not developed until after the opening of the century, but now is a characteristic school of the typical university. While the core of its service and offering has been and continues to be training for professional accountancy, the more progressive collegiate school of business is attempting, not without some success, to serve as a higher school of learning for the development of professional managership. While many areas of service have been professionalized, management and entrepreneurship still are largely in the rule-of-the-thumb, take-a-chance stage. The collegiate school of business has dedicated itself to overcoming this weakness in our economic structure. (See also BOOKKEEPING AND ACCOUNTANCY EDUCATION; BUSINESS TRAINING; CONSUMER EDUCATION; DISTRIBUTIVE EDUCATION; OFFICE PRACTICE; SECRETARIAL TRAINING; TYPE-WRITING.) H.A.T.

BUSINESS ENGLISH. Before 1920, the majority of commercial high school curricula included a one-term or two-term course in Business English, usually offered in the first year. It consisted essentially of a study of models of business correspondence, practice in letter writing, and related corrective work in good usage, functional grammar, spelling, punctuation, and use of the dictionary. With the incorporation of the commercial curriculum into general secondary education as a series of elective courses, and the realization that all high school students should develop ability to write effective business letters, Business English as a separate course has largely disappeared and its content has been merged with that of the regular curriculum in written English. In some high schools, the departments of English and secretarial studies agree on uniform arrangement and punctuation of

formal parts of letters, use of the same manual of style, gradation in psychological and social complexity of various types of correspondence ranging from simple letters of application to adjustments of claims, and on standards in technical English at various levels. The belief that the English of business has a distinct diction and style has been generally abandoned. S.S.

BUSINESS MANAGER, SCHOOL —
 See ADMINISTRATION, SCHOOL.

BUSINESS TRAINING. This subject is usually presented in the ninth grade of schoolwork. It was instituted in the early 1920's to give specific junior clerical training because of the recognition that junior workers were no longer receiving positions as bookkeepers and stenographers. The shifting upward of the age of initial employment from 14 to 17 or 18 has eliminated the need for formal vocational business education at the junior level. The subject is now taught as a general orientation course in business to give students a better understanding of the basic facts about business and its functions. While it is generally required only for business students, leaders in business education feel that it should be a universally required subject similar in its purposes to general science, general mathematics, etc.

There are now several hundred thousand students enrolled in business training in the eighth, ninth, or tenth years of school in this country. Business training therefore ranks with shorthand, typewriting, and bookkeeping as one of the most frequently taught business subjects. The course is known under such titles as Elementary Business Training, Junior Business Training, Introduction to Business, Everyday Business, Functions of Business, etc. The modification of the title does not reflect corresponding differentiation of subject matter. (See also: BUSINESS EDUCATION; SECRETARIAL EDUCATION.) H.A.T.

CAFETERIA, SCHOOL. The school cafeteria represents an important development of the last twenty years. At the beginning of the twenties very few schools provided special space for lunch room activities. By 1940 few schools were being built without such space. Moreover, the school lunch trend has reached down into the elementary school and even into thousands of one-room rural schools. Often rooms planned for other purposes have been utilized for lunch rooms. The movement gathers momentum year by year.

While there is great variety in plant facilities, cost of lunches, and size of the operating unit, there is fairly general agreement in objectives for school lunch rooms or cafeterias. The movement began, according to its competent historian, Mary DeGarmo Bryan, as charity for the feeding of poor children, developed as a convenient service for pupils and faculty, and finally attained its present status as an indispensable feature of the health and teaching programs for all school children. Its functions now include all of the various services by which its development was marked.

A powerful incentive to expanding school lunch activities came from the provision by the Federal Government of free food from the Surplus Commodities Corporation. This trend toward free school lunches for indigent and undernourished children has moved along with, and in some cases independently of, the general trend toward providing warm, nourishing lunches on a cost basis for all children who wish to avail themselves of the opportunity.

Commonly accepted on all levels of the public school are the following functions for school cafeterias and lunch services:

(1) By providing nourishing food to combat the effects of malnutrition in some of the

children and to maintain in all the children the vigor necessary for school activities.

(2) To provide social training for all pupils.

(3) To correlate teaching with experiences of children which center about food.

(4) To interest the community in the nutritional needs of children and to give parents whatever instruction is possible.

School cafeterias are planned to operate without profit and with some items of overhead, such as space and utilities, paid by school funds. Nourishing lunches are therefore provided at low cost. It is likely that the school lunch movement will continue to gain under the influence of two important trends: (1) the consolidation of school districts which increases the distance between school and home for more pupils, and (2) the growing interest in scientific nutrition during childhood years. (See **LUNCH HOUR ACTIVITIES.**)

CAMBRIDGE PLAN—See PROMOTION.

CANADA, EDUCATION IN. Under the British North America Act, which is the Constitution of Canada, the provinces are autonomous in education. One notable exception to that autonomy is the provision that religious minorities in any province be guaranteed the continuance of the rights which they enjoyed in that province at the time at which it entered the Dominion of Canada. Thus there is no single Canadian school system; there are nine distinct systems, one for each province.

The Dominion government has never been entirely free from educational responsibilities: it is responsible for the education of its wards, the Indians; for the schooling of chil-

dren living in the parts of the Dominion which are not included in any province (e.g., the Yukon); and for training for service in the armed forces. During World War II this last responsibility led not only to a great extension of military training, but also to the establishment of "war emergency classes" to prepare workers for war industry. Indeed, the interest of the Dominion government in vocational education is long-standing. It has granted substantial subsidies to encourage agricultural education (1913) and general vocational training (1919). No conditions were imposed upon the provinces which accepted the earlier subsidies; in the later grants, the only stipulation attached was that the province accepting the federal grant must match the amount received by an equal amount from the provincial treasury to be devoted to the same purpose. The depression years saw similarly financed schemes of youth training under Dominion-Provincial auspices. In "war emergency classes", however, the Dominion government not only aided in establishing a specific type of training, but also regulated and controlled that training. A new Vocational Training Coordination Act (1942) empowered the Dominion government to set up and maintain schools, without reference to provincial governments, "to fit persons for employment for any purpose contributing to the conservation or development of the natural resources vested in the Crown in the right of Canada." Clearly the national emergency of World War II and the need for a planned reconstruction program led the Federal government into a direct invasion of a field formerly regarded as reserved for the provinces. The Education Branch of the Dominion Bureau of Statistics continues to do much valuable work in the compilation and publication of educational information.

Despite the existence of distinct provincial school systems, Canadian education is characterized by similarities rather than by diversity. In a typical province, education is entrusted to a department of government, headed by a minister of cabinet rank. He is advised by a staff of employed experts, of whom the chief is styled deputy minister or superintendent of education. The provincial contribution to the cost of education is often surprisingly low; the bulk of the cost is borne by local taxation usually based upon the

assessed value of real property. The chief aim in the distribution of the provincial contribution is to equalize opportunities. The provincial departments of education exercise a high degree of control over courses, textbooks, teachers' qualifications, and supervision.

Rural education presents a persistent problem in a sparsely-settled country like Canada. The one-teacher, ungraded school too often constitutes the child's only opportunity of securing a schooling. Such schools must attempt to offer not only a fairly long elementary course, but, frequently, a secondary course as well,—a course that in the nature of things must be rather attenuated and incomplete. Isolated families, beyond the reach of any schools, are served by travelling teachers; by correspondence courses; and, especially in the western provinces, by radio lessons. Over most of rural Canada, the traditional small school district, with its limitations of resources and of vision, is still the common unit of school administration. Everywhere, however, there are signs of a coming better day. Until 1942 Alberta was the only province to enact legislation reorganizing the whole province into larger school areas. Several other provinces have permissive legislation to encourage the voluntary merging of small districts into more adequate school areas. Nova Scotia and Ontario report substantial progress in this direction; Manitoba has long had many "consolidated" districts, and British Columbia has conducted significant experiments in the amalgamation of school districts. It is common practice to elect *ad hoc* boards of trustees to administer local schools; in several provinces, if these boards fail to act or if they request release from their duties, "official trustees" are appointed by the provincial department of education. This often proves to be a first step toward the complete union of neighboring districts.

All the provinces have overhauled their curricula within recent years. Courses have been multiplied and liberalized; an honest effort has been made to adjust the program to the needs of the child and to integrate the school with the community. The traditional control of secondary school curricula by the universities has been relaxed. External examinations have been reduced in frequency and in importance. Activity methods are empha-

sized. Vocational education has made huge strides; in Ontario one-third of the high school pupils are enrolled in vocational schools; the new intermediate household science schools of Quebec illustrate a general tendency to make education serve the practical needs of everyday life.

CARDINAL PRINCIPLES OF SECONDARY EDUCATION. The cardinal principles of secondary education represent a declaration of objectives designed to emphasize the fact that "complete living" rather than college admission or mental discipline is the end of education. The principles are seven in number: "health, command of fundamental processes, worthy home membership, vocation, citizenship, worthy use of leisure, and ethical character". They were formulated in 1918 by the Commission on the Reorganization of Secondary Education and represent the first attempt by an authoritative body of educators to apply this philosophy of "complete living" to the secondary school.

These principles have been widely and frequently referred to in educational circles but they have had little direct effect on school practice. This is no doubt due to the fact that they are a vague "disorderly miscellany." They fail to present divisions of "complete living" that serve as tangible focal points around which instructional practice can revolve. (See SNEDDEN in the references below.)

They do, however, represent a contribution to education; for in an attempt to improve upon them much thought and effort has been expended, thus focussing attention on the validity of the "school as preparation for living" objective.

CASE STUDY. A method of using specialized techniques for gathering information, determining difficulties, and planning and effecting treatment for the problems of an individual needing help. This method makes the individual's needs the center of the social workers' concern, and the individual's rehabilitation the objective of all their efforts.

Case work, often called social case work, is the means by which the objective is attained. It includes all of those processes which develop personality through adjustments, consciously and unconsciously effected, between the person needing help and his social environment. If social case work is to be effective, the individual's needs must determine not only the objective but the method of treatment.

The factors responsible for the person's problem are internal as well as external. The individual's adjustment depends not only upon environmental, economic, and physical factors but also upon his emotional attitudes, the degree of emotional stability, the interplay of emotional factors between himself and the people in his environment, and his feelings about himself and his situation.

When the individual's problem has been surveyed and accepted as one amenable to social case work treatment, this treatment is initiated from the earliest contact of the client with the social worker, that is, in the interview situation. Formerly, it was thought necessary to obtain a complete history of the client's life, in its personal, family, educational, occupational, and other phases, before treatment was begun. It is now recognized that history taking as an entity must be discarded, and that archaic designations of study, diagnosis, and service or treatment must be interpreted not as separate phases, but as one intermingling, continuous process. Treatment begins in the first interview; as the worker learns something about the client, she is at the same time stimulating the latter to seek out the solution of his problem.

As the social worker learns more about the

client and the nature of his maladjustment and needs, she may obtain the cooperation of a psychologist to determine the client's abilities and potentialities, or, in cases involving severe emotional disturbances, she may consult with a psychiatrist for an evaluation of the client's emotional difficulties, inasmuch as case work deals with social problems rather than with those of psychopathology.

The method of the case study has had considerable influence on the procedures followed by child guidance clinics (*q.v.*) in the study and treatment of children with behavior problems. This procedure implies that each child presents a distinct problem and that he must be studied as an individual if the clinician is to understand the physical, psychological, social, educational, and other factors which have contributed to the child's difficulties in adjustment. The case study implies, too, that the child must be seen as a total personality, with emphasis placed on his total needs and adjustments rather than on the specific incidents which may have led to his referral to the clinic. Since the treatment is based on the facts which come to light during the process of working with the child and his environment, it can be planned only on an individual basis. The case study approach makes it difficult, if not impossible, to think of treatment patterns which are appropriate for the truant, the delinquent, the feeding problem, etc. Instead, it suggests that treatment is most likely to be successful when it accepts the child as the center of interest and then concerns itself with understanding his problems so thoroughly that he may be helped to develop more satisfactory means of solving his problems.

The case study method, in a modified form, can be utilized by teachers in the study of a maladjusted child, not so much for the purpose of treatment but in order to understand the factors influencing the child's behavior, and, in turn, to modify the school's handling of the child. CASE WORK IN SCHOOLS—See CASE STUDY; SOCIAL SERVICE ACTIVITIES IN SCHOOLS.

CATECHETICAL METHOD. The *Catechetical Method* is a method of teaching that proceeds on the basis of question and answer, both printed for the student. The term comes from the Greek *Katekhetes*, an oral teacher, as Socrates was. It has survived in the typical church catechism but otherwise is mainly of historical interest. When Alcuin undertook the instruction of Pepin, the son of Charlemagne, he prepared a lengthy catechism for him, exemplified by the following excerpt:

Q. What is writing. A. The custodian of history.

Q. What is speech? A. The interpretation of the soul.

Q. What produces speech? A. The tongue. The main objection to the catechetical method as a teaching procedure is that it puts a premium on the exact reproduction of set answers, and therefore exercises little but rote memory. The formal recitation is an outgrowth of this method. The following excerpt from a nineteenth century textbook typifies this application:

Q. What is the planet, on which we live, called? A. It is called the Earth.

Q. What is the shape of the Earth? A. It is very nearly round.

Q. Do we live on the outside or the inside of the Earth? A. On the outside.

The catechetical method has little place in the modern school, which belittles rote memory and emphasizes instead the student's ability to use his factual background as an aid in solving problems. W.R.

CATHOLIC EDUCATION—See ROMAN CATHOLIC EDUCATION.

CATHOLIC PAROCHIAL SCHOOL. A Catholic parochial school serves the children of a parish, is supported by parish funds, and is under the immediate control of the pastor. As a unit in the diocesan system, the school is under the jurisdiction of the bishop of the diocese. It is a day school and is usually coeducational. The erection and maintenance of such a school in each parish was required by a decree of the Third Plenary Council of Baltimore, in 1884, in keeping with the Catholic belief that secular and re-

ligious instruction should not be dissociated.

The Catholic parent is required by Church law to send his child to a Catholic school to secure a Christian education. Instruction in secular and religious subjects is cared for by members of religious orders. The program of studies parallels that of the public school, except for intensive instruction in the tenets and practices of the Church. Content and special subject requirements, as outlined in State law, are rigidly observed in each diocese. The entire program is regulated by the Christian spirit, so that "Religion may be in very truth the foundation and crown of the youth's entire training." In short, the task of the parochial school is to develop Christian character.

There are 7,056 parochial schools in the United States (1940). Units are in operation in each of the 112 dioceses and in every state. Sixty thousand teachers care for approximately 2,000,000 pupils. One hundred and forty religious orders supply teachers. Fifty-five per cent of all Catholic children of elementary school age are registered in parochial schools. (See CATHOLIC EDUCATION.)

F.M.C.

CAUSAL METHOD (Research)—See RESEARCH METHODS IN EDUCATION.

CAUSE AND EFFECT TEST—See OBJECTIVE TESTS AND EXAMINATIONS.

CENSUS, SCHOOL. The school census involves the counting of all children of given ages (specified by law as *census age*), the recording of certain data about these children, and the filing of these data for permanent use.

Originally, hired enumerators visited each home in the community and listed on sheets the names of children of census ages, their ages, dates of birth, addresses, names of parents, and similar data. These data were tabulated for reports to the state department of education and no further use was made of them.

Trends at present aim at maintaining a permanent and continuous census. Data from the enumeration are recorded on cards; these cards are filed either alphabetically or by streets, or both. Each card may have data for an entire family, in which case the census is known as a family census. The more

usual procedure is to have each card contain data for only one child.

When an attempt is made constantly to keep the data corrected on the census cards (individual or family), a continuous census is had; this act of correction involves not only keeping the data on the cards up-to-date but having cards in the file for all children of census age who, at a given moment, live in the school district.

Devices for keeping the census files up-to-date are: (a) match census cards with enrollment cards each semester; (b) report all pupil transfers to the census office; (c) organize a "civic service league" in which a pupil is made responsible, in each city block, for reporting all changes of residence; (d) secure reports on change of residence from the police, operators of moving vans, attendance workers, bureau of vital statistics, and similar agencies; and (e) plan a house-to-house enumeration every five years.

Census ages still vary greatly among the states. Originally they tended to range from 5, 6 or 7 to 21 years of age, since the census was used chiefly as a means of distributing certain state school funds. Present day uses are much broader in scope and the demand is being made for a continuous census from birth to at least 18 and to possibly 21 years of age.

A continuous census from birth to 18 or 21 years of age makes possible the following advantages: (a) a more adequate school building program, (b) more effective year by year planning of the educational program to care for gains or losses in enrollment, (c) more effective enforcement of school attendance regulations, (d) a guard against losing track of families that need financial aid in order to care properly for their children.

CENTRAL AMERICA, EDUCATION IN. *The Ideals.* Education in the Central American republics has passed through a three-fold process. The period of colonization

was characterized by the hegemony of religious congregations in educational matters. The period of struggle for independence was one of unsystematic education, the product of private initiative. The period of later political organization has been characterized by the tendency to convert education into an essential service and function of the state.

In its pedagogic aspect, this process signifies the transition from the dogmatic to the activity, rational school. In its social aspect, it signifies the recognition of the right of all to culture and to an education; no longer is this a privilege of the ruling classes alone. In its administrative aspect, it signifies the progressive control of educational services by the state through a centralizing system.

Nevertheless, private schools are permitted and are even subsidized by the governments, provided they help make up the deficit of the national schools and submit to official inspection.

All of these republics accept an ideal of education frankly democratic and have implanted, without violence, some principles which in other countries have been the result of violence and struggle. Equal educational opportunities for all races and social classes, compulsory and free education, and movements toward secularism and co-education can serve as examples. Nevertheless, in Nicaragua teaching is largely in the hands of the Catholic fathers, and neither in Haiti nor in the Dominican Republic is co-education permitted.

The Methods. Dogmatism, verbalism, and the passive attitude of the student are in general being replaced by the procedures of a comprehensive and active education. But in many cases the desire to modernize methods and techniques, with poor or inadequate means and without the previous preparation of proper personnel, has resulted in confused situations in which the old was abandoned without being able to accomplish the new. Almost everywhere newer systems—the Decroly system, the Winnetka plan, the Dalton plan, center of interest procedures—have been tried. Sometimes appreciable results were obtained; at other times the failure of these attempts was attributed to the limitations of the new methods when actually inability or the haste with which these attempts were made was at fault.

CENTRAL AMERICA, EDUCATION IN

In this trend to modernize education *Costa Rica* has distinguished itself by introducing new methods very gradually, *Guatemala* by being the first to try them in experimental schools before prescribing them for the entire system, and *Panama* by calling biennial conferences for the discussion of the new techniques.

Organization and Institutions. All the Central American republics have an office of Secretary of Education, which assumes the direction, administration, and inspection of public education.

Costa Rica, which prides itself on having more teachers than soldiers, promulgated in 1937 its present fundamental law of instruction, which embraces the area from pre-school education to high school and professional education. A central commission is in charge of carrying out the law and of defining the activities of educational institutions.

There are three kinds of elementary schools, the traditional, the active, and the vitalized (*las tradicionales, las activas y las vitalizadas*). Secondary education is arranged in two divisions, one for the development of general culture and the other for professional education. Higher education is given in the Schools of Law, Medicine and Obstetrics, Pharmacy, Commerce, Engineering, and Architecture.

In 1940 *Costa Rica* used for public instruction 21 per cent of the general funds of the state, and brought to its schools 11½ per cent of the population.

Guatemala promulgated its *Organic Law of Public Instruction* in 1937, with the principal purpose of extending primary culture. Schools were founded in centers of population where there were more than ten children, and in barracks, prisons, and in public institutions. Industrialists and large landowners were required to maintain schools in factories and on estates. Secondary education produces bachelors in science and letters who are prepared for primary teaching and for entrance into the University. The law of 1937 added the Faculty of Economic Sciences to the University.

Guatemala allots 12½ per cent of its general state funds to education, but not more than 5½ per cent of its population attends the institutions of learning.

El Salvador is waging a fight against

the disproportion between its scanty means and its relatively large population and is concentrating its efforts toward the extinction of illiteracy. It has organized traveling instructors as one way of achieving this aim.

Its educational system is organized into *Jardines de la Infancia* (Kindergartens) for children from 3 to 6, primary and higher elementary schools, secondary schools, and rudimentary schools. Secondary education is almost completely in the hands of private institutions. For the preparation of teachers there is a normal school for each sex.

Nicaragua has separated administrative from technical direction. *The Secretariat of Education* has kept for itself the administration and inspection, and has delegated technical authority to the *Chiefs of Services* and *Inspectors*. Police officials and port officers assist in the fulfillment of educational obligations.

Secondary education is in its infancy and although the preparation of teachers requires four courses, the only special studies offered are those of theoretical and practical pedagogy. The majority of the teachers are prepared in the pedagogical institute of the *Hermanos de las Escuelas Cristianas* (Brothers of Christian Schools).

Nicaragua appropriates 14 per cent of its state funds to education. This amount is supplemented by a system of taxes and fines administered by the *Juntas* of Fathers.

Panama's Office of the Secretary of Education is in charge of administration. Pedagogical matters are under the jurisdiction of the District Inspectors. The division of General Inspection established in the secretariat unifies the work of the inspectors. The government made effective use of the opportunity to contract foreign teachers and to send students to other countries.

Elementary education, regulated by a special decree, is almost completely in the hands of the state. On the other hand, secondary and professional education are carried on in private schools as numerous as those of the government.

Panama allots 16 per cent of its budget to education and approximately 12½ per cent of its population attends its schools.

Cuba is the educationally least centralized of this group. The Department of Education has almost no other duty than that of admin-

istration of a general character. Technical matters are entrusted to a Board of Superintendents, which unifies the work of the local school officials. Each municipality has a Board of Education which directs its schools, levies its funds, appoints its teachers, exercises disciplinary functions, and provides buildings and materials.

There is an intense modernizing movement, influenced partly by the United States and partly by Europe through influential publications in English and Spanish. Examples of these influences are the *Crèches*, very similar to the Belgian model, the *Kindergartens* and the higher primary schools, similar respectively to the nursery schools and the junior high schools of the United States. For higher professional studies there is the autonomous University of Havana and its affiliated Institutes of Languages, Commerce, and Pedagogy, and the Technical Industrial Schools, which are the best endowed institutions of learning in the country.

Twenty per cent of the budget is allotted to education and 12 per cent of the population attends school. Nevertheless, private instruction performs an essential service, since the majority of secondary and vocational schools, which are very varied, are private institutions.

Haiti has a very simple system. The territory is divided into areas directed by inspectors responsible to the central administration. Although Haiti recently created Normal Schools, the only requirements for teaching are an aptitude freely acquired and good conduct.

The state spends 10 per cent of its budget on education, and but 5 per cent of its population attends its schools.

Haiti is at present devoting considerable attention to the reconstruction of education at all levels, including vocational education, and in the past two years (1941, 1942) has sent a large number of its educational personnel to the United States for specialized preparation.

The Dominican Republic controls education (with the exception of the university) through a *Consejo Nacional de Educación* (National Board of Education) which has very wide powers limited only by the Constitution and the general laws of the country. The office of the *Secretary of Education* func-

tions as the executive and inspection agency. The country is divided into departments, at the head of which are the *Intendentes*, and into educational districts in the control of *Inspectores*. There is in addition a *Technical Office* accessory to the office of the Secretary.

The schools, no matter of what grade, can be official, i.e., state controlled; or semi-official; i.e., state subsidized. The private schools are maintained by their own funds; they are, however, subject to inspection.

Primary instruction, almost completely under the state, is given in rudimentary, primary elementary, and primary secondary schools. Secondary education and teacher education are given in normal schools. Vocational education is given in various special schools. Higher and professional studies are conducted in the autonomous University of Santo Domingo, which recently created a faculty of philosophy for studies essentially theoretical and cultural.

Eleven percent of the budget is spent on education. F.S.

CENTRAL TENDENCY. Educational data are frequently obtained as a set of scores, ages, or other measures for a group of pupils. It is often desirable to obtain a single measure which may be used to represent such a set of measures a typical or representative measure, the statistical name for which is *central tendency* or *average*. There are three such averages commonly used in treating educational data: the *arithmetic mean* (called the *average* in nonstatistical parlance), the *median*, and the *mode*. The most familiar measure of central tendency is the arithmetic mean, which is simply the sum of the individual measures divided by their number. If the measures are arranged in order from highest to lowest, there is a point such that half of the measures are above it and half are below. This point is called the median. Ordinarily one of the measures will occur with a greater frequency than any of the others; this is the mode.

When dealing with a set of ungrouped scores, such as the weights of fifteen children, each of these three measures of central ten-

CENTRAL TENDENCY

dency is easily determined in accordance with the above definitions. To indicate how measures of central tendency are computed when they are grouped in a frequency table, we shall illustrate the use of these measures in terms of the distribution of teachers' salaries in the high school of a small city. The f (frequency) stands for the number of teachers in the school receiving salaries somewhere within the interval range indicated to the left.

Salaries in \$'s	f
3,500—3,999	3
3,000—3,499	0
2,500—2,999	3
2,000—2,499	6
1,500—1,999	18
1,000—1,499	6
<hr/> TOTAL	<hr/> 36

The mode here is in the \$1,500 to \$1,999 interval and is taken to be best represented by the mid-point of the interval, \$1,750. The median is at a point which leaves 18 of the salaries below it and the other 18 above it. When the actual salaries are spread out seriatim, this point can be located precisely; but in a frequency distribution it must be located roughly by interpolation. It is $12/18$ or $2/3$ of the interval length (\$500) above the \$1,000-\$1,499 level, and so is \$1,833.33. The mean is obtained by multiplying the values of the mid-points of the several intervals by their respective frequencies, summing these products, and dividing by N (the total number of persons). Its value here is \$2,000.

The explanations of the three measures of central tendency indicate that they do not mean the same thing and would normally not be used interchangeably, although all three satisfy the basic requirement of being representative of a group of scores. Though it is relatively easy for any person to learn to compute these measures of central tendency, especially with the aid of the specific instructions contained in all standard textbooks on educational statistics, it is more difficult to develop the degree of understanding that leads to the selection of the most appropriate measure to be used in a given instance. The nature of the situation indicates which measure of central tendency should be computed. Generally there is no sound reason for computing more than one measure of central tendency for the same group of measures.

If it is desired to use a measure of central tendency in the computation of which all the measures have contributed, the arithmetic mean would be the measure to use. Thus, in the illustration cited above, the mean salary of \$2,000 was computed on the basis of the salaries earned by all the teachers. If it is desired to find the measure that an individual would be most likely to get, the mode should be used.

The mean is the most reliable (See RELIABILITY) of the common measures of central tendency, and is customarily used in refined statistical procedures. The mean is a mathematical quantity in that it is the result of mathematical processes and it is subject to mathematical processes. For example, the mean of combined distributions can be computed accurately by mathematical processes from the means of the several distributions. The median and mode are not the result of mathematical processes, nor are they subject to them. But if the distribution is skew, or if there are a few scores that scatter widely at the upper or lower end of the distribution, the mean may give a distorted picture of the situation. Thus, the three high salaries in the distribution reproduced above affect the mean to a marked extent. Where there are such extreme scores at only one end of the distribution, it may be preferable to use the median. Moreover, the median may be used advantageously when it is not convenient or feasible actually to measure the extreme cases, for the value of the median turns only on a knowledge of the number of variates in the sample and a knowledge of the quantitative values of those near the middle of the distribution. The median is probably more meaningful for typical school situations. It may be preferable for such situations also because it is easier to compute, and the typical school use of data calls for less accuracy than do research needs. The mode is useful, especially when speaking to laymen, to give a vivid picture of the prevailing tendency in the scores. Thus, to say that more teachers in a given high school get salaries of \$1,800 than any other one salary amount (that is, to say that the modal salary is \$1,800) may be the most illuminating way in which the salary situation can be described to laymen.

Although a measure of central tendency

typifies a group of measures, by itself it cannot give an adequate picture of the group of measures. For that purpose it must be accompanied by a measure of the extent to which the measures vary from their central tendency. (See VARIABILITY.) C.C.P.

CENTRALIZATION IN EDUCATION.

Centralization refers to the policy of concentrating the support and control of education in the hands of the central government of a state or nation. The opposite policy of leaving the support and control of education to local authorities is called *decentralization*. The tendency in most countries of the world is toward a highly centralized organization of education with a hierarchy or military gradation of administration and supervision. The educational system is invariably headed by a national or state chief school officer with authority delegated downward through minor officials. In practically all countries, educational organization is centralized in a minister of education who is a member of the government cabinet. France provided a good example of a completely centralized system of education with a Minister of National Education at the head of the entire system. One weakness of a highly centralized system of education was exemplified in France where frequent changes in the ministry might result in radical changes in educational policy. Every school regulation in Germany from the establishment of the first Prussian Ministry of Education down to the present time has been in the direction of a more thoroughly centralized educational system. The Third Reich, under Hitler, completely centralized education in the hands of the Ministry of Education in Berlin, as a means of upholding the government, preserving national culture, and maintaining the new industrial, economic, and military new order.

In the United States, there has never been

an organization of the school system on a strongly centralized federal basis, and even in the states strong centralized state school organizations have not been substituted completely for local autonomy, although there have been definite trends toward greater state centralization. For many years, educational leaders and organizations have been advocating the establishment of a Federal Department of Education with a secretary who is a member of the President's cabinet. There have been suggestions of a National Board of Education which would determine nationwide policies and practices in education. In the various states the trend is definitely in the direction of state support and control of the public schools.

Centralization has both its advantages and disadvantages. The first advantage is administrative efficiency, through increased economy of operation, more careful planning and co-ordination of policy, and greater utilization of expert services. A second advantage is the equalization of benefit which standardization may accomplish. The increased mobility of population makes it necessary for the schools to standardize the training of pupils as citizens, not merely of the local community, but of the state, the nation, and even the world. A third advantage arises from the possibility of sharing widely the benefits that come from concentration of wealth in certain areas. Some communities are financially unable to provide acceptable school programs; other communities have more than enough. Centralized responsibility for financing the educational program will provide greater equality of educational opportunity.

But centralization also brings serious disadvantages. Most important is the waning of popular interest, and the stifling of local initiative, thus curtailing the freedom to experiment in adapting education to local needs and conditions. Increased centralized support may result in a decreased sense of responsibility for education on the part of the local tax-payers. Centralization tends to cause the people to demand more and more educational services from the government without realizing that they must in the end pay the bill. Finally, under centralized administration, any error or mistake has far-reaching consequences, and undesirable political manipulation may affect all education

seriously, particularly when the administration desires to perpetuate itself.

Probably neither complete centralization nor complete decentralization is the solution of the problem. Perhaps the major problem of the administration of American education is not to decide at which level of government complete responsibility for all education will be placed, but to study educational needs thoroughly and then determine which level of government, local, state, or national, can best carry on particular educational functions.

CENTRALIZED SCHOOL. Definition.

The term centralized school may be applied to a large school plant housing a comparatively large number of children and usually organized as an elementary, junior high, and senior high school. The centralized school is often the result of the consolidation of school districts and the abandonment of small schools. The term consolidation or consolidated school (*q.v.*) may be applied to the reorganization and enlargement of administrative units and attendance units; whereas the centralized school is a school conveniently located in a large attendance unit. It frequently involves the transportation of children, especially in rural areas.

Values and Limitations. The values of centralized schools are largely inherent in the types of programs made possible when relatively large numbers of children are brought together in one school building. This is perhaps more apparent in the upper than in the lower grades. It is possible in such schools to provide for the special services of health, recreation, guidance, etc., to an extent that would not be possible in smaller decentralized schools. The limitations of centralized schools have become apparent with the problem inherent in increased programs of trans-

portation. There is some evidence that in certain sections of the country an attempt has been made to centralize schools more than necessary, and that the various groups of children might be as well provided for in smaller elementary schools and in centralized high schools.

CHARACTER AND PERSONALITY TESTS. There are many reasons, both theoretical and immediately practical, why adequate tests of character and personality would be a most desirable contribution to human welfare. Such tests would force the issue of character education (*q.v.*) by making it imperative that the results of character education be clearly demonstrated. The value of such tests to educators would be inestimable in aiding them to evaluate their efforts. Adequate tests of character and personality would make wise vocational guidance much more possible, since qualities of personality are so important in determining vocational choice and adjustment. In the development of such tests theories of personality would be clarified. The experimental values of such tests are apparent. In short, if we could have tests of growth in character and personality that truly mirrored such growth, that could be depended upon and that were practicable of administration, a contribution of great magnitude would have been made to education.

Few, if any, educators or psychologists contend that we now have such tests. There are a multitude of tests and rating devices which purport to measure *aspects* of personality. The volume of production of such tests is suggested by the fact that the *1940 Mental Measurements Yearbook* lists sixty-nine tests

in this field, although not all of these were produced in the two-year period to which the *Yearbook* is chiefly devoted. That confidence in the tests so far developed may have weakened is suggested by a recent publication of the American Educational Research Association which reports that "notwithstanding continued activity in the production of tests of personality and character . . . there seems to be a decline in the application of tests in this area." (1. p. 7)

Skepticism about the usefulness of current personality and character tests rises from a number of sources. The most serious basis of criticism springs from the fact that the proper evaluation of personality must involve the measurement of the whole person's reaction to situations. This reaction includes the person's inner feelings as well as his overt behavior. Faced with a task of this magnitude, most test makers have resorted to measuring only aspects of the person's behavior, and even to measuring aspects of behavior in closely controlled and often very artificial situations. How difficult it is to put together these measurements of aspects of personality may be seen by selecting, let us say, six personality tests of various sorts, securing the results, and then trying to put the various results together into a picture of the person. If the investigator has a vital interest in the person in question (perhaps is trying to counsel him), he will probably be impressed by several facts. First, that a battery of the very best tests still does not yield all the necessary facts about a person. Second, that most of the tests depend upon self-reporting by the subject, thus leaving one to wonder how well we can understand the person from what he tells us about himself. Third, that the test makers have usually been vague about the validation of their tests, and only fairly successful in showing that the subject will react to the test consistently from time to time. Fourth, that almost none of the tests really measures behavior in like-like situations.

The tests of personality and character that are available have been classified in many different ways. A simple classification based on what the tests purport to measure is as follows:

1. Measures of environment. While not tests of personality as such, instruments de-

signed to provide accurate information about the economic and cultural background of the person are useful in understanding the person. One of the best known and most widely used measures of environment is the Sims Score Card.¹⁰

2. Measures of behavior, under controlled and uncontrolled conditions. Such measures include (1) tests to measure the extent to which a child will cheat under a given teacher; e.g., the Character Education Inquiry Tests of Honesty¹¹; (2) behavior rating scales that require careful checks as to particular behavior manifestations like the Haggerty-Olson-Wickman Scales¹²; and (3) the more recent projective methods which seek to interpret motives, attitudes and needs by the analysis of the drawings, play, dramatic activities, voice, gestures, and even handwriting of the person. The Rorschach (*q.v.*) "inkblot" technic is one of the most novel and widely used of the projective methods. (1, pp. 84-87)¹³

3. Measures of ethical knowledge. These abound in number, are fairly easy to construct, and have all too often been called "attitudes" tests. One of the better moral knowledge tests is that developed by the Character Education Inquiry.¹⁴

4. Measures of attitudes and opinions. These have, for the most part, been paper and pencil tests which ask the person to represent his attitude by checking alternative solutions to ethical issues. Obviously, the chance of misrepresentation is great. Probably attitudes can more accurately be inferred from carefully observed behavior. An important and useful series of attitudes tests covering specific fields are those of Thurstone.¹⁵

5. Measures of "general" or "emotional" adjustment. This has been a type of test in the production of which test makers have been very prolific. The tests are usually of the self-reporting sort, the subject's statement of how he feels about many things being interpreted to reveal his adjustment to life's conditions. So much depends upon the honesty of the subjects' report that the use of such tests is seriously limited. The Bell¹⁶ adjustment inventory is one of the more widely used instruments of this sort.

6. Measures of interests. Such tests suffer from the handicap of self-reporting methods

but can yield helpful information for the guidance of the individual and for determining dominant interests in a group in planning educational programs. The Strong Vocational Interest Blank,¹⁷ for example, has proved useful in guidance work.

7. Measures of "the whole person." There are really no such measures, and may never be—certainly no single, simple measure. However, the case method, by means of which all that can be learned about a person is brought together in systematic form, is no doubt the most useful approach to the study of an individual. (7, pp. 267 ff.) (See also ANECDOTAL BEHAVIOR JOURNAL; CASE STUDY.)

In spite of all the difficulties in the measurement of personality and character, a careful worker, using carefully selected tests, can learn much more about a subject than would be possible by the traditional method of "general impressions." Constant attention to the fact that a person is a person, and not the sum of a number of qualities (no matter how well defined these may be), will keep the educational or psychological worker from being misled by fragmentary measurement of personality and character. Recognition of the fact that all measurement is the refinement of observation will also help to guide the worker in the selection of instruments of measurement.

CHARACTER EDUCATION. There is almost universal acceptance of the belief that education should achieve moral outcomes. "Character" as an end of education is included in most statements of educational aims. This has always been true. What character is, what its manifestations should be in conduct, how good character may be fostered, what kind of educational plan will most surely lead to the best character development—upon such questions there is much disagreement, confusion, and uncertainty.

The most prevalent concept of character is that it is an inseparable quality of personality, that *character is personality evaluated according to the moral demands of a society*. If character is the expression of personality in those aspects of living that have moral or ethical significance, then "character education" is any effort to improve the moral quality of human conduct.

The objectives of character education will vary with the ethical codes of the society in question. In American democracy character has commonly been judged by a two-fold test:

First, does the person in question live in accordance with the best interests of the greatest number? This is the social test. It expresses the demand that education produce

good citizens. Democracy requires not only that her citizens be enlightened, but also that they be men and women of good will.

Second, does the person in question live happily, is he well adjusted to life's conditions and demands? This is the personal test. Democracy values human personalitiy. Education has not achieved its goals unless the educated are happily adjusted persons.

Under these two related goals there may be classified numerous specific ethical aims of education. The Tenth Yearbook of the Department of Superintendence of the National Education Association⁴ has enumerated many of these aims. When an effort is made to be specific about the objectives of character education difficulties arise. One of the most persistent difficulties involves individual freedom of action versus social compulsion, discipline, and control. There can be no doubt that, despite a growing tendency to stress the development of individual freedom of moral choice, character education remains in practice chiefly an effort to get the child to accept in conduct the moral code of the group into which he is born. This is especially true of the young child. However, a distinct advance in character education in the past few decades is the recognition that the self-control and self-determination we expect in the adult comes through a long process of education and that opportunities for freedom of choice should begin in childhood.

The methods of character education naturally tend to conform to the concept of character and the objectives of character education employed by the educator. This is clearly seen in educational practice. Knowledge of the right was for so long regarded as a paramount requisite of good character, that the teaching of moral principles has long been a chief method of character education. This was consistent with the "knowledge is power" philosophy of education. With the increased concern over the evident lack of relation between knowledge and conduct, character education has shifted in method to conduct-centered approaches.

Efforts at character education that begin with or stress the inculcation of ethical knowledge have commonly been called the "direct method" of character education. Efforts which stress conduct in life-like situations, the development of attitudes and habits

through practice, have usually been called the "indirect method". This distinction is artificial and has led to much needless discussion. Modern psychology and educational experience has demonstrated the validity of the "learning to do by doing" principle, especially when such emotionalized results as attitudes and ideals are sought. As a result, modern character education has tended to draw away from formal lectures and sermonizing and to seek the achievement of an intellectual basis for good conduct through discussion of live moral issues closely related to the life of the child. Conduct problem cases with the "what would you have done" challenge have proved useful in evaluating both the experience of others and one's own related experiences. Similarly, problems of conduct that arise within the school or in the community are utilized as content for discussion. There is ample evidence that moral knowledge can be taught, but that its effect is slight unless it is taught with opportunity for practice. (See JONES³.) Greater opportunity for such practice is found in the newer educational programs that are evolving in the modern school.

The evaluation of character education has lagged because of the inadequacy of available tests of conduct, attitudes, and other aspects of character. There is general agreement among educators that the ultimate test of education is the improved conduct of the educated. But to measure conduct changes as complex as those involved in such traits as fair play, openmindedness, honesty, and the like, is obviously a task running far beyond the scope of ordinary paper-and-pencil tests. That schools attempt it is evidenced by the fact that school report cards, almost without exception in the elementary schools, and frequently in secondary schools, carry teachers' evaluations of a large variety of character traits. (See CHARACTER AND PERSONALITY TESTS.)

Character education should be related to the total educational effort. It has already been pointed out that character cannot be educated apart from the whole personality. This suggests the need for regarding every aspect of education as having moral potentialities. That there is some doubt that an educational program will of necessity achieve character ends is shown by the fact that sev-

eral states have laws requiring that moral instruction and character education be conducted in the schools. Religious educators and church leaders have frequently questioned the adequacy of secular character education and insisted that character comes chiefly through religious experience and training. Another significant problem is involved in the character-educating influence of such potent agencies as the radio, the motion picture, the press, commercial amusements and the like. How the school can cooperate with the home in developing the child's character is another phase of the problem that deserves more attention. It seems clear that the social well-being of a democracy could most surely be maintained by a better coordination of the efforts and influence of the large variety of character-forming agencies to which the child is subjected.

CHEATING. Cheating may be defined as the attempt an individual makes to attain success by unfair methods. In school, cheating usually takes the form of giving or receiving help on tests or examinations, cribbing, or turning in written work done by another. Investigations show that the home is the most important factor in conditioning attitudes toward honesty, also that cheating is more prevalent among dull persons than among the brighter or average ones. It may be due to many causes, both social and individual. Conflicting social standards in the home, school, and community, and the immature attitude that unfair methods of achieving success are all right if undetected, undoubtedly are responsible for much dishonesty, as are extreme selfishness on the part of the offender, inability to face possible failure, and desire for power and recognition. Undue emphasis upon marks and grades; the overstimulation of competition; uninteresting curricula; and stern, unjust, or careless teachers also promote dishonesty.

Cheating is sometimes symptomatic of a child's emotional maladjustment or conflict, and as such is far more significant than the teacher may realize. There are even some children who cheat in such a manner that detection cannot possibly be avoided; such children may be using cheating as a device to incur punishment in response to a psychological need. Where cheating results from causes such as this the problem is one that calls for treatment by the psychiatrist or psychologist—not by the teacher.

Fortunately, most instances of dishonesty have no such complex background. Teachers have found the following techniques to be effective in dealing with the common problems arising from cheating: attaching social approval to honest rather than to dishonest behavior; associating dishonesty with unpleasantness; teaching the child to realize that some failure in life is inevitable and to face such failure as a problem to be solved rather than to be evaded; adapting tasks to the child's needs, interests, and abilities; emphasizing tests as teaching rather than measuring devices; avoiding lax examination conditions which encourage cheating; and employing teachers who are well adjusted emotionally.

CHECK LIST. A check list consists essentially of a set of items each of which is to be checked off, if present, in accordance with the particular purpose involved. Its major function is to focus attention on the items to be covered. Ordinarily the relative importance of the individual items is disregarded, although a weighting system may be employed. Among other uses, it may serve as a questionnaire (*q.v.*), as an instrument for recording behavior observations, and as a sort of scale, yielding a score.

For example, "Place an X before each of the following activities in which you participated during the past week:

- _____ 1. Listened to the radio.
 - _____ 2. Attended a lecture.
- etc."

CHEMISTRY, TEACHING OF. — See SCIENCE, TEACHING OF.

CHICAGO PLAN. The College of the University of Chicago differs in four important ways from the conventional liberal arts college. Its program begins two years earlier than that of other colleges, permitting students to enter after two years of high school instead of four. Its course of study consists of an integrated system of courses covering the principal fields of knowledge rather than an assortment of courses chosen by the student himself. It measures the achievements of students and determines their eligibility for the Bachelor's degree by comprehensive examinations rather than by adding up credits earned in separate courses. It expects young men and women to complete their work for the Bachelor's degree at the age of eighteen or nineteen.

The differences between The College of the University of Chicago and other colleges are not accidental, nor are they the result of a desire simply to be unique. For fifty years the University has been concerned with providing the kind of basic, general education which everyone ought to have no matter what occupation or profession he proposes to enter. In order to provide this kind of education efficiently the University separates sharply its program of liberal education from its programs of specialized or professional training. Its first president proposed in 1891 that the first two years of college should be devoted to general education, and that the completion of the work of these years should be marked by the award of a diploma. In 1931 the University was reorganized upon the recommendation of President Hutchins to provide separate administration, under The College, for the work of the freshman and sophomore years, leaving specialized and professional training to the upper divisions and professional schools of the University. In 1932 the last two years of the University High School were taken into The College, and since 1937 students who have completed two years of high-school work at Chicago or elsewhere have been admitted to The College to begin a four-year course of general education. Finally, in January of 1942, The College was empowered to award the Bachelor's degree for the completion of general education

at the end of the traditional sophomore year of college.

The core of the College curriculum consists of general courses in the natural sciences (biological and physical), the social sciences, and the humanities. Students do three years of work in each of these three fields. As they acquire information and learn to think for themselves, they are expected to develop the ability to communicate their knowledge. A three-year course in writing is, therefore, added to the general subject-matter courses. Students normally pursue these four lines of study concurrently through the first three years of their College work, taking comprehensive examinations in the natural sciences, the social sciences, the humanities, and in English at the close of each year. At the end of the student's College work he takes a one-year course in principles and methods designed to assist him to integrate the studies he has pursued. The remainder of his fourth year is open for the pursuit of special interest courses or for laying the foundation for later specialized training.

In working out the Chicago Plan of college education, the faculty has been concerned with: (1) the content of liberal education; (2) the adjustment of the subject matter of education to the previous training of the student and to his possibilities of intellectual growth; and (3) the development of the kind of person and citizen a college should aid in producing. It has been necessary again and again to ask: What should be taught? How should it be taught? And to what end?

The body of knowledge which has been accumulated in the course of Western civilization is so vast that only a small part can be included in a college curriculum. Careful selection and balancing are essential. The faculty of The College has rejected the easy solution of this problem commonly adopted by colleges—the elective system, under which students are forced to make their own selection of subjects. To present them with this difficult task is to assume that they already have the wisdom which they have come to college to acquire. The elective system is sometimes defended on the ground that it affords students a valuable freedom. But freedom to make a choice when the results of the choice are not clear is a doubtful benefit. Colleges which allow the student to choose

CHICAGO PLAN

the subjects he will study generally force him to attend class and to perform a multiplicity of routine assignments. The College of the University of Chicago reverses this procedure. It does not follow a free elective system, but it gives students considerable freedom with respect to class attendance and class work.

The Chicago faculty has worked out over a period of more than ten years a system of general courses which cut across the many special fields in the University curriculum and consist of a careful selection of fundamental materials in these fields. The course in the physical sciences, for example, includes basic instruction in physics, chemistry, mathematics, astronomy, geology, and physical geography. The general course in the biological sciences provides a knowledge of the plant and animal kingdoms; the course in the social sciences brings together the study of social problems, political science, and economics; and the course in humanities includes work in history, literature, art, music, and philosophy.

The content of liberal education has been but one of the concerns of The College. A good college course must do more than provide a survey of the present state of knowledge. The body of that knowledge is not only vast but constantly changing. It is more important that a college student should learn to understand the ways in which facts are acquired and the processes of reasoning by which they have been interpreted than that he should memorize a body of currently accepted information. All real knowledge includes a grasp of reasons. College education must, therefore, consist fundamentally of the examination of arguments and the practice of reasoning.

The general courses at Chicago emphasize the methods of acquiring knowledge of a subject. For this purpose students in the general courses meet with instructors in small discussion sections to analyze the materials given them in the lectures or presented in their reading assignments. It is assumed that students have not really understood a fact or a theory until they have examined the reasons for holding it and are able to justify accepting or rejecting it.

This kind of training should begin as soon as the student's faculties have matured suffi-

ciently to make it profitable. It should be as concentrated and efficient as possible, so as to allow students who expect to go on into medicine, law, teaching, scientific research, or other professions to begin their specialized training at a reasonable age and to make it possible for others to enter upon non-specialized work without waste of time.

The University of Chicago believes that the best time for a student to get a basic, general education is between the ages of fifteen and eighteen. Nine or ten years of sound preliminary schooling should be enough to prepare for it. Most young people are sufficiently mature at what is now conventionally the junior year of high school to profit from it. There is, indeed, a natural break at what is now for most students the middle of a high-school course, as has long been recognized in the development of junior and senior high schools.

Students who finish the work of the College are awarded the Bachelor's degree, which has traditionally marked the completion of a program of liberal education. During the last two generations, collegiate programs for the Bachelor's degree have included more and more specialized work, and with the growth of the elective system have become more and more haphazard, until the earlier significance of the degree has very generally been lost.

The requirements for the Bachelor's degree at Chicago are met by passing comprehensive examinations. When a student has completed his preparation in a subject, either by formal class instruction or by independent study, he takes an examination prepared by the Board of Examinations. The papers are read anonymously and are graded by readers other than the instructor in the course. To earn the Bachelor's degree a student who has credit for two years of high-school work (including two years of mathematics and two years of a foreign language) must pass comprehensive examinations in the natural sciences, the social sciences, the humanities, English composition, and the relationships of the subjects he has studied. Modified programs are available for students who enter with credit for more than two years of high-school work. A high-school graduate can ordinarily earn his degree in about two years. (See LIBERAL ARTS COLLEGE.) C.H.F.

CHILD ACCOUNTING. The keeping of instructional and executive records of the individual child during his school life is referred to as *child accounting*. The scope of child accounting as developed by AYRES¹ in 1915 included the recording of information concerning school census and enrollment; the enforcement of compulsory attendance; issuance of work permits; the determination of age-grade status of pupils; and the keeping of certain instructional, appraisal, and administrative records. More adequate recording of information became an important phase in the administration management of large numbers of pupils in a complex school system. Moreover, state compulsory education laws, child labor laws, and the practice of distributing state aid on the pupil basis, kept attention focused on this phase of administration.

The term was given a wider scope by MOEHLMAN² through the inclusion of such activities as the maintenance of industrial relations, placement and follow-up of pupils, and the editing of school publications.

A still broader scope of the term was later implied by HECK³ in the term *pupil personnel* which he defines as "those services whereby all children of school age are 'kept track of,' caused to attend school, and so studied that they are aided in making the maximum good use of the abilities which they have." This definition involves both a quantitative and qualitative aspect of pupil personnel work, whereas by the narrower definition of child accounting reference was made only to the quantitative aspect.

Other writers have since included various phases of guidance service in the term pupil personnel; as for example the volumes of the *Review of Educational Research*,⁴ entitled *Pupil Personnel Guidance and Counseling*, and the book by STRANG⁵ entitled *Pupil Personnel and Guidance*. Both include the recording phase or child accounting, but they go far beyond the quantitative in the determination of the kind of information to be recorded and the use to be made of the information in pupil development and adjustment.

With the increasing emphasis on pupil guidance in recent years, the term child accounting has given way to broader terms and is now little used. MOEHLMAN⁶ suggests that

the term may still be used, but should be narrowed to the original definition to include the recording of information concerning children in the schools. W.C.R.

CHILD CARE. In a broad sense *child care* refers to the general efforts and purposes of all social agencies giving attention to child welfare in the family and community. Child care by social agencies is aimed to safeguard children and improve the influences upon them in the areas of family relationships, housing, health, recreation, child labor, dependency, physical handicaps, and social security.

The attention of child care agencies is usually directed first to family conditions affecting the child. More than half the children in our country live in families with not enough income to care properly for them. Child care agencies are concerned with, though not directly responsible for, the improvement of housing and the elimination of slums. The provision of adequate recreation and health facilities is also the concern of child welfare workers. Great progress has been made in recent years in improving the health of children, particularly of infants less than one year old. Child labor laws may be included under this head; it is essential to the proper care of children that young workers should be protected against dangerous occupations, unreasonably low wages, and excessively long hours.

Special assistance is necessary for many dependent and handicapped children. In caring for these groups, public welfare departments and private agencies now have the help of the provisions of the Federal Social Security Act. Special agencies deal with the probation and supervision of delinquent children.

Such are some of the outstanding examples of child care usually thought of in connection with that term. There is need for more careful planning in developing such services to prevent duplication of effort, and at the same time afford to all children the medical, educational, and social services essential to safeguard the future citizens of our democracy.

The changes that have taken place in the nature of institutional provision for child care, especially for the care of neglected and dependent children, reflect the progress that has been made in our understanding of child psychology and in society's attitude toward children. As recently as the beginning of the 19th century, there were many communities that saw no need for differentiating between the care of dependent children and the care of all other wards of the state. As a result of this attitude, orphans and other dependent children were accommodated in the "poor house", along with the beggars, the blind, and insane. The segregation of dependent children and the erection of orphanages and other "homes" for children constituted, therefore, a revolutionary step in child care. In time, these large institutions were also being criticized, largely because they were so large that little attention could be given to the individual abilities and needs of children and because life in these institutions bore little resemblance to the kind of family life for which these children were supposedly being prepared when they left these institutions for adult living in the world.

The *cottage plan* represented a step in the direction of more normal provision for children. In the cottage plan type of institution, the children were housed in small cottages, often accommodating about twenty-five children, presided over by a cottage father and a cottage mother. Even the cottage plan failed to satisfy those who regarded the normal family as the ideal environment for children, for, as these critics pointed out, where was there the family that consisted of twenty-five boys all between ten and thirteen years of age? It continues to be difficult, moreover, to find a sufficient number of cottage fathers and mothers who have the personal qualities and professional abilities needed for their responsibilities and who are willing to serve for the relatively small remuneration usually paid for this type of work.

Two other types of adjustment have therefore become increasingly popular. Where the child's family can continue to function if its financial burdens are eased, some form of subsidy may be granted, either in the form of a widow's pension or as a direct subsidy from the community, or a charitable agency. Where the child's family is not available or is not the appropriate environment for the child, he may be boarded with a "foster" family and thus live in a family environment that resembles that of more fortunate children.

Today, provision for child care takes many forms. There are special institutions of the orphanage type, cottage plan institutions, foster homes, and subsidies to the child's family. The type of provision that is made for an individual child depends on the facilities that are available in the community and on the special needs of the child. (See DEPENDENT CHILDREN.)

CHILD-CENTERED SCHOOL. The expression *child-centered school* was popularized by Harold Rugg and Ann Shumaker in their book by that title which presents an appraisal of the new education. The book is a "Critique of Progressive Education in the United States" and the story of the early progressive schools.

The child-centered school typifies the reaction against mass education, formal discipline, "subject-storage curricula," and the lock-step of the traditional school. The child-centered school stresses freedom vs. control, child initiative vs. teacher domination, activity and experiences vs. passive listening and the formal recitation, child interest vs. routine and restraint, creative self-expression vs. imitative reproduction and repetitive drill, personal and social adjustment vs. regimentation, child growth vs. subject mastery.

Some "progressive" schools and "progressive" parents tend to go to such absurd extremes in their reactions as to discredit the whole progressive education movement. As a

result, the child-centered school often connotes license vs. freedom, superficiality vs. power, caprice vs. plan, disrespect for authority vs. ability to use the best experience of the race and guidance by elders. In its better sense, it stands for emphasis on child study, child development, child guidance, and adjustment of the child to his natural and social environment. (See ACTIVITY PROGRAM; PROGRESSIVE EDUCATION.) J.J.L.

CHILD GUIDANCE CLINICS. Child Guidance Clinics (also known as Child Guidance Centers, Institutes for Child Guidance, and Bureaus of Child Guidance) are agencies concerned primarily with effecting the adjustment of children who are handicapped by emotional difficulties, present in either the parent or child, by inequalities between their capacities and the social and educational demands, and by other traumatic environmental situations. The clinic in carrying out its function of improving the adjustment of children does so through (1) the study and treatment of individual children, (2) the co-operative study of cases with social agencies, juvenile courts, etc., and (3) an educational program designed to disseminate mental hygiene concepts in schools, and other child-centered agencies.

Children are referred to the clinic for such disturbing behavior as disobedience, rebelliousness, marked aggression, stealing, truancy; for such personality difficulties as withdrawal from social contacts, inability to get along with other children, shyness, nervousness, and fears; and for such school difficulties as inattention, indifference, repeated failure, etc. Clinics also assist other agencies in working out placement and adoption plans. The age range is from infancy to late adolescence. Child guidance clinics are primarily community clinics, i.e., financed by Community Chest Funds, or private endowments. However, some clinics are connected with general hospitals, while others, in the larger educational systems, help integrate all child guidance services in the schools.

The average staff of these clinics consists of a psychiatrist, who is usually the executive head, a psychologist, a part-time pediatrician, one or more psychiatric social workers,

and a clerk. The cooperation of these various professions in understanding and treating children's problems assures a broader service than could be rendered individually.

The psychiatrist assumes the principal responsibility for diagnosis and treatment. In clinics where the services of a pediatrician are not available, he also conducts the physical examination of the child and makes recommendations for physical care. He works primarily with the child, determining the emotional attitudes and reactions. When psychiatric treatment is indicated, he sees the child at regular specified intervals for that purpose. He also deals with adult problems when they are closely related to the difficulties of the child being studied, and may even focus his treatment on the parent, rather than the child. The psychologist tests the child's capacities and achievements, may be responsible for a remedial teaching or tutoring program, makes school contacts when the significant disability is academic in nature, and in a limited number of clinics has the responsibility for treatment of behavior problems. The psychiatric social worker studies (through home, school, and office interviews) the underlying social and emotional factors in the home, school, and community. The material derived from the combined studies is discussed at a staff conference which usually includes the school principal, teacher, and any pertinent social agency worker. In the conference, treatment plans are evolved. These may consist of psychotherapy for the child given by the psychiatrist, treatment of the parent by the social worker to effect changes in attitude and handling of the child, adjustment of the school program, and interpretation of clinic findings to the school.

Studies of juvenile delinquency have repeatedly revealed the fact that children brought into court have, as a rule, been known as behavior problems by schools and other community agencies for some time previous to their arraignment in court. It seems reasonable to suppose that any program of prevention begun early enough will save not only the usefulness of the individual to society, but also the more extensive outlay of public money for mental hospitals and prisons. Public-spirited citizens are beginning to use their influence to increase the number of Child Guidance Clinics which at

present are far too few to serve even those already applying for help, while they must ignore the larger number of children who need help but who have not been referred to the clinics. (See MENTAL HYGIENE.) M.S.Q.

CHILD LABOR. Child labor is essentially a denial of child education, and is the counterpart of compulsory education. The employment of children is regulated directly by child-labor laws and indirectly by compulsory school attendance laws.

State Legislation. By and large, apart from Federal legislation, the regulation of child labor is a problem of establishing by state legislation standards of age, education, physical condition, maximum hours, and hazardousness of specified occupations. While there is no uniformity among the states on these matters, at present thirteen states (including 41% of our population) approximate a 16-year minimum standard for all employment during school hours. Except for industrialized agriculture, a 14 to 16-year minimum for employment during school hours prevails generally throughout the United States; but more than 60% of the child workers are employed in agriculture.

Federal Legislation—Early History. As early as 1884, organized labor made a plea for an amendment to the Federal Constitution empowering Congress to regulate child labor and the first proposal was introduced into Congress in 1906. As finally adopted in 1916, the first Federal Child Labor Law (39 Stat. 675) prohibited the shipment in interstate commerce of goods produced in mines or quarries employing children under 16; or in mills, factories, etc., employing children under 14, or in industries in which children between 14 and 16 worked more than 8 hours daily or more than 6 days weekly. Over the brilliant dissent of Justice Holmes, and by a 5—4 vote, the Supreme Court held this Act unconstitutional, it being

beyond the federal authority to control interstate commerce. *Hammer v. Dagenhart*, 247 U. S. 251 (1918). A second Act in 1919 (40 Stat. 1138), placing a 10% tax on profits of mines employing children in violation of the standards of the 1916 Act was likewise declared to be an unconstitutional exercise of taxing powers. *Bailey v. Drexel Furniture Co.*, 259 U. S. 20 (1922).

To legalize such statutes, Congress in 1924 adopted a proposed child-labor amendment empowering Congress "to limit, regulate and prohibit the labor of persons under 18 years of age." The proposed constitutional amendment requires the ratification of three-fourths of the states; to date, and despite the tremendous pressures brought to bear by religious, economic, and political groups, 28 states have ratified the proposed amendment. In 1939 the Supreme Court ruled that the constitutional amendment was still alive for ratification and that the mere passage of time was not fatal to its ultimate approval by the requisite number of states.

Federal Legislation—Present Status. Congressional action, however, has not awaited final approval of this amendment. The Walsh-Healy Act of 1936, 49 Stat. 2036, 41 U. S. C. 35, bars employment on government contracts exceeding \$10,000 of boys under 16 and girls under 18. The Jones Sugar Act of 1937, 50 Stat. 903, 54 Stat. 571, 7 U. S. C. 1131a, conditions payment of federal benefits to farmers on the prohibition of child labor under 14, except for members of the immediate family; and on the prohibition of child labor between 14 and 16 for more than 8 hours daily. Violations are punished by deductions from benefits of \$10 per child per day.

The greatest advance came with the Fair-Labor Standards (Wages and Hours) Act of 1938, 52 Stat. 1067, 29 U. S. C. 212, which accomplishes what the first two federal child labor acts failed to do. It forbids the shipment in interstate commerce of goods produced by child labor under 16 in covered employments, or under 18 in occupations declared by the Children's Bureau to be hazardous. The Act does not apply to agriculture, intrastate commerce, street trades, or to children between 16 and 18, thereby leaving untouched the greater portion of child labor.

The Supreme Court upheld the constitutionality of this Act in 1941, *U. S. v. Darby*, 312 U. S. 100, 61 S. Ct. 451, specifically overruling the first child labor case and opening the field for control of child labor on the federal level.

While the recent decisions of the Supreme Court of the United States restore to the Federal government power to deal with child labor, such authority so far is limited to the scope of otherwise permissible federal activity (interstate commerce, agricultural benefits, and government contracts). The necessity for the thorough-going powers which would be given Congress by the constitutional amendment still prevails.

CHILD PSYCHOLOGY. Child psychology is not a different psychology from that of other age levels; it is the psychology of a developing personality from its earliest stages through the beginning stages of adolescence (*q.v.*) or to that age when the attainment of maturity becomes the focus of investigation. The scope of child psychology today includes every aspect of child growth and behavior, e.g., the establishment of habits of eating, sleeping, and elimination, growth in size and in motor and manual coordination, the acquiring of speech, the development of the emotions, the learning of patterns of social behavior, as well as the growth of intelligence and interests and the learning of informations and skills.

Theories of child psychology always have been closely related to theories of original nature and of learning. When these began to be checked by observation and experimentation the child study movement developed.

Since every phase of child life is included in child psychology, children are studied at

home, at school, at play, with adults, with other children of the same age, and with children of different ages. The content of child psychology now includes a vast amount of factual data together with various hypotheses, of which some have gained a high degree of consensus among psychologists, while others still form the subject of heated controversy. Facts have been gathered by and for those interested in child training, those interested in the personality adjustment of children, and those interested in formulating the principles of child growth.

Much of the work in child psychology has been concerned with the establishment of norms of size and of behavior for different age levels. Ideally, development should be studied longitudinally if one is to determine whether the curve of growth is uniform for different children and whether there is an orderly progress through definite stages. Studies which are continued over a period of years are, however, difficult to undertake for a large sample. The norms of performance at various age levels usually are obtained from a group of children of mixed chronological ages who can be divided up into subgroups representing each age being studied. One of the most elaborate scales of early development is Gesell's series of standardized norms for infants from one to thirty months of age. These norms cover the fields of motor, language, adaptive, and personal-social behavior. Norms from other studies, however, vary considerably. The norm variations are due partly to the fact that the number of children studied by a single investigation at any one age level are often exceedingly small, being fewer than ten in many cases. These investigations are nevertheless important in that they point to the existence of very wide individual differences among children in the rate of their development.

Much less difference has been found in the order of development, particularly in the order of motor development. It is agreed that the vast majority of children can walk upstairs alternating the forward foot long before they can walk downstairs in such manner, this latter accomplishment being reached, on the average, between the fourth and fifth year. Most children can jump off the floor with both feet before they can hop on one foot. They can make distance jumps and jump from heights, and can acquire consid-

erable skill in climbing, before they can skip. About half of kindergarten children have been found to be able to skip in rhythmic fashion with alternating feet. Block-building has been observed to progress from crude, unsteady structures not meant to be representative of any object, through only slightly recognizable structures which were definitely planned by the child to represent real objects, to careful symmetrical construction which show an advance in imagination as well as in manual skill. The degree of imagination displayed in such activities reveals especially wide individual differences.

The fact that there is a fairly orderly progression of motor development has led to the construction of scales of development which have been used as measures of intelligence in the early years of childhood. The unevenness of developmental curves, however, keeps such measures from being accurate. There are a number of mental tests used for preschool age children, such as the Kuhlmann Tests of Mental Development, the Merrill-Palmer Scale, the Minnesota Pre-School Scale, and the Pintner-Patterson Performance Tests. (See INTELLIGENCE.) Only a minority of psychologists grant high validity to the mental age assigned to a child who is tested before the age of five.

With the establishment of nursery schools (*q.v.*) and nursery clinics in connection with colleges and other institutions, the amount of trained observation of children has increased greatly. It has become possible also to set up experimental situations in which children are exposed to selected stimuli. Observation in free situations is often controlled by the time-sampling technique where each child is observed for the presence or absence of certain selected behaviors during short periods of time (often not more than five minutes) distributed over a succession of a considerable number of days or weeks. The observers usually are trained and tested for the reliability of the data they record.

Besides these controlled observations, verbatim records and full descriptions of what children say and do both in free and in experimental situations have proved exceedingly helpful in the study of children. Such records are full enough so that they can be arranged in different ways for later analysis and interpretation without too much distortion resulting from their being lifted out of

context. Those investigators who are particularly interested in the social development of children find this method most useful. It gives them an opportunity to plot the relationships among the same group of children in different situations and with different adults present. The growth of certain traits in any one child can be studied qualitatively as well as quantitatively. It becomes easier to locate the factors which are influencing the behavior of each child.

Some conclusions borne out by all such group behavior records are that patterns of behavior differ from child to child even in preschool years, and that though these individual patterns change as the child grows, it is the pattern that changes rather than a single trait. The child's awareness of other people increases as age increases. The child develops from an egocentric to a sociocentric being. This does not mean that he changes from a selfish to an unselfish creature. It merely means that he learns to take the other fellow's behavior and point-of-view into account in making his own plans. Obviously, sociocentric thinking must be present before sympathetic and unselfish behavior can be displayed, but a person who understands another person's point-of-view may use that understanding to further his own ends at the expense of that other person.

Records of children's early behavior in group play almost entirely free from adult interference definitely have disproved Rousseau's theory that children are born good and that it is society which makes them bad. It is evident that society does "make" their social traits but it can make them good or bad. Different teachers (representatives of society) are found to have quite different effects on the social behavior of children, for example on the amount of aggression and sympathy they develop.

Direct questioning of children offers another method of obtaining data. The younger children are necessarily tested orally and individually, and many psychologists prefer the individual oral method even with older children who can read and write. This preference is due to the difficulty that children often have in interpreting the question asked them in the way that the examiner meant it to be understood. Oral questioning can make certain that the child does get the desired meaning. Piaget (*q.v.*) used the method of

individual questioning even with children of twelve to fourteen years of age, when he made his extensive investigations of children's language development, their reasoning, their conception of the world, and their moral judgment.

These investigations of Piaget resulted in a heated controversy as to whether children and adults think in radically different ways or in essentially the same manner. It was Piaget who proposed the term "egocentric" as descriptive of children's thinking and "sociocentric" as descriptive of adult thinking, which he believed was reached by most children about the age of thirteen or fourteen. Investigations which followed those of Piaget have, on the whole, disproved both his age norms and his clear dichotomy between the thinking of children and of adults. Egocentric and sociocentric thinking both have been found to be present at all age levels. The degree of egocentricity depends largely upon the newness and difficulty of the relationships which are being reasoned about. Naturally, the same problems set before both young and old will result in a much greater degree of egocentric thinking on the part of the young. Illogical thinking also is prevalent with both young and old whenever thinking from a point of view other than one's own means accepting a condition (even hypothetically) that is emotionally distasteful.

Whether children learn differently from adults also has been a lively topic of controversy among those who do not accept a single-principle theory of learning. Some psychologists believe that the conditioned-response description of learning fits children better than does any other description. In so far as childhood is a time when many fears and likes and dislikes of specific things are being established—and the theory of conditioning seems to be at its best in describing such learnings—this theory of conditioning will describe adequately how children acquire behaviors in this area.

That children learn mostly by imitation and drill has been assumed by adults who have given children tasks to perform which were so far beyond their level that the children could not solve them. On the other hand the drill tasks set them (usually verbal drill) were within their power of memorizing, if not understanding, and the method of testing their learning measured only their

ability to recall. Other investigators claimed that when children did solve problems, they solved them by random trial and error, not by reasoning. However, there are sufficient investigations today to show that at a very early age children learn by reasoning if the problem before them is one not too difficult for their mental-age level. The most accepted conclusion is that children and adults learn by essentially the same process under psychologically equal conditions.

The investigation of children's interests, their likes and dislikes, has been another fertile area of investigation. This has been done predominantly by the questionnaire (*q.v.*) technique, both oral and written. It has been found that interests change with both age and environment (physical and social) and that sex differences in interests arise at an early age. These sex differences are themselves different in different environments and different eras, thus showing the influence of the culture upon them.

Recently, one of the problems receiving a good deal of experimental investigation has been the relationship between maturation and learning. McGraw's experiments with twins during their first few years of life are well-known. One of these boys was trained in various activities as early as possible by being provided with equipment and stimulation, while the other was left alone as much as was considered advisable, and did not begin his training in some of the activities until a year or more after his brother. The advantages of the earlier training proved negligible in somatic skills common to all mankind, such as walking, and in activities, such as tricycling, which were found very difficult by the twin who started his training early. For some years after the experiment was over, the earlier-trained twin did maintain superiority over his brother in certain performances where the growth of the body did not necessitate a readjustment in technique. Differences in the attitude of daring and in grace of movement were also found to favor the earlier-trained brother. Other similar studies have also pointed to the conclusion that for some activities it is well to wait for a certain degree of maturation before subjecting a child to specific training. Attention is now being centered on means of determining when a child is ready to receive training in this or that area. Combinations

of physical and mental tests plus specially developed readiness tests are already being used as the criteria for determining when formal reading and arithmetic instruction should begin. (See **READING READINESS**.)

Projective techniques (*q.v.*) are being used both for the study and for the release of children's emotions. Toys which are representative of both objects and people and which the child can use to represent specific persons in his environment are given to him to play with as he wishes, though he is carefully and often unobtrusively observed. At other times the experimenter may enter the play and guide it into certain channels, noting the child's reactions to the play situation thus set up. Observations have been made as to how children handle their frustrations and their aggressions and how they work out social situations with dolls, toy houses, toy automobiles, etc. The degree of emotional repression already present in these nursery school years is thus estimated. If the inhibition is judged to be excessive, it is hoped that the play material will in time bring some release on a symbolic level. At the same time parents and teachers are given interpretations of this play behavior so that they can guide better their own relations with the children.

The acquirement of adult taboos and adult prejudices has also been studied more directly. Race prejudice has been found to be nonexistent in the earliest years and its later development is fostered both by the general mores of the child's social group and by direct teaching and punishment for transgression of the parent's wishes. Even in southern United States, the general mores are not strong enough to develop a high degree of race prejudice among young children, and even in children of elementary school age, until these prejudices are reinforced by the direct teaching of adults. Other attitudes are similarly acquired both from the mores and from the particular adults who are in authority over the child.

A very large part of child psychology concerns itself with the mental hygiene of childhood, with children's need for love and security and status. Child guidance is interpreted as meaning guidance of the whole child in all phases of his development. His emotional adjustment to a world that will bring him many frustrations is regarded as

only one side of the guidance procedure. The converse side requires that parents, teachers, and other adults adjust their demands upon the child and their relationships to him in such a way that he will not have more frustrations than he can handle.

The extent to which modern educational thinking stresses the importance of relating educational practices to the child's needs, interests, and abilities has made the study of child psychology an increasingly important part of preservice teacher education. The emphasis in educational psychology traditionally has been placed on the child as a learner, with the attendant stress on such topics as transfer of training, curves of learning, growth of intelligence, etc. Recent textbooks in educational psychology reflect the change in educational thinking by paying considerable attention to such topics as children's interest, personal and social adjustment, and growth. The need for understanding the psychology of the child as a person rather than only as a student has been more apparent in the education of the elementary school teacher than in that of the secondary school teacher. There is as yet little evidence that a corresponding degree of interest in the personal adjustments of the college student is a recognized part of the preparation of college teachers. CHILD STUDY MOVEMENT — See **CHILD PSYCHOLOGY**.

CHILDREN'S BUREAU OF THE UNITED STATES DEPARTMENT OF LABOR. The Children's Bureau was established in 1912, and carries on a comprehensive program of child welfare by conducting research, providing consultation service, and

publishing popular and technical bulletins on problems relating to children in industry, child development, treatment of delinquents, and the care of dependent, neglected, and handicapped children. Under the provisions of the Social Security Act of 1935 the Children's Bureau cooperates with state public welfare agencies in establishing, extending, and strengthening, especially in predominantly rural areas, child welfare services for the protection of homeless, dependent, and neglected children and those in danger of becoming delinquent. The Chief of the Children's Bureau must approve plans for maternal and child care submitted by states before allotments of federal funds may be made. Three divisions within the Bureau administer the maternal and child welfare provisions of the Social Security Act: (1) The Maternal and Child Health Division, including a public health nursing service, (2) The Crippled Children's Division and (3) Child Welfare Division.

CHILDREN'S CHARTER. The White House Conference on Child Health and Protection (*q.v.*) in 1930 drew up a statement of its fundamental principles in the form of a Magna Charta or Bill of Rights for childhood. This Children's Charter, as it was called, consisted of a beautifully formulated presentation of nineteen requirements which the conference considered a minimum for a healthy and happy childhood:

Point I claims the right of every child to spiritual and moral training with the aim of building strong character.

Point II claims the right of every child of understanding and the protection of that personality which makes him different from all other individuals in the whole fabric of society.

Point III claims the right of every child to love and the security of paternal care, or its nearest possible substitute.

Point IV claims the right of every child to preparation for life and protection at birth; and for every mother: preparation for the giving of life and protection against unnecessary hazards in child-bearing.

Point V claims the right of every child to

health protection in his home, in the school he attends, and in the community in which he lives.

Point VI claims the right of every child to health instruction and wholesome recreation.

Point VII claims the right of every child to home environment which provides for the child's needs: for his safety, for privacy, space, and place to play.

Point VIII claims the right of every child to a school environment equipped for sanitation, safety, and comfort.

Point IX claims the right of every child to a community which provides for his needs.

Point X claims the right of every child to an education which incorporates preparation for the obligations and responsibilities of parenthood, citizenship; and for parents: dissemination of the accruing knowledge to prepare them for parental responsibility.

Point XI claims the right of every child to an education which considers him as an individual and prepares him both for living and for earning.

Point XII claims the right of every child to safety from accidents to himself and to his parents.

Point XIII claims the right of every handicapped child to his rightful education, development, and protection.

Point XIV claims the right of the child hitherto known as delinquent to intelligent and humane treatment.

Point XV claims the right of every child to that security and protection against dependency which can come only with a decent family income.

Point XVI claims the right of every child to protection from labor before the full span of childhood is reached.

Point XVII claims the right of the rural child to health protection and cultural and social advantages.

Point XVIII urges the stimulation of those organizations and groups which have sprung up to supplement home and school in the molding of youth and in providing for youth's interests.

Point XIX urges the need of machinery in districts, counties, and communities to carry out these health and welfare rights outlined in the Charter.

CHILDREN'S DISEASES — See COMMUNICABLE DISEASES OF CHILDHOOD.

CHILDREN'S LITERATURE. Literature for children is not limited to those books written and designed expressly for children but includes all prose and verse that appeal to the young. Indeed, very little of the vast store of folk and fairy tale, of legend and of nursery rhyme, was created for the young. Until recently this traditional lore plus selections from adult literature plus dull tales specially written to embody some moral, formed almost the entire content of approved books for children. Outside of folklore there was little that could be called literature and that at the same time was suited to the child's reading ability, to his level of understanding, and to his interests. About the middle of the 18th century, John Newberry published what was probably the first English book written for the amusement of children and which took account of printing and illustration in terms of the young reader.

The increasing number of children's books printed in the next century, however, concerned themselves not with children's amusement but with their instruction, both factual and moral. The narrative part of the child's story book merely held the information together or formed the context in which the moral lesson could be conveyed. Though Grimm's Folk Tales had appeared in English before that time, it was not until the publication of Hans Christian Andersen's stories toward the middle of the 19th century that fairy tales assumed a predominant place in children's books. Neither Grimm nor Hans Andersen had written for an audience of children, and many of their tales are unsuitable for the young reader, either because of content or complexity.

There has been a controversy, recurring at intervals, as to whether children should be given much fanciful literature. Today the multitude of books written for children, and published in a format and with illustrations designed especially for them, includes a great variety of content both realistic and fanciful. Among books which have received the Newberry medal, awarded since 1922 for the most distinguished children's book of the year, are

stories both fanciful and realistic. Outstanding among modern books are picture books for children who cannot read as well as for those who can. There is now a special award (Randolph Caldecott Medal) for the most distinguished American picture book of the year. Much of the new juvenile literature is newly written by authors and poets who are beginning to be known as children's writers, though a number of them have reputations in the adult field as well as. However, a considerable number of the new books are old tales rewritten for modern boys and girls, and printed and illustrated in keeping with the rapid progress that has been made in the graphic arts. A children's room or section in the public library with a children's librarian in charge; Children's Book Week celebrated in November; the Junior Literary Guild; a Book Buying Club for boys and girls; a page or more of reviews of children's books appearing regularly in the book review section of the Sunday newspapers—all serve to bring before the young and their parents the good children's books now coming regularly off the American press. There is also a slow but increasing tendency to establish libraries in elementary schools, which to date have suffered from a dearth of reading material.

CHILE, EDUCATION IN. A high degree of centralization is the characteristic feature of the Chilean educational system, as it is that of the Chilean State. According to the ideas of don Andrés Bello that education should radiate from the upper to the lower classes of society, all branches of education were organized in 1842 under the direct authority of the University of Chile. In 1860, primary education, and in 1879 secondary and higher education, though keeping some of their former links with the University, were reorganized as separate entities more directly controlled by the Ministry of Educa-

tion. The reforms from 1927 to 1931 greatly contributed to articulate the different branches of education into a better integrated system.

At present, all primary, secondary and special schools are under the supervision of the Ministry of Education, which supports and operates all public schools, and controls and partially subsidizes private ones. The University of Chile has enjoyed relative autonomy since 1929, and retains control over the examinations given by the professional schools of private universities for diplomas recognized by the State. The Ministries of Defense, Agriculture, Land and Colonization, and Justice operate a few educational institutions—Military and Naval schools, elementary courses for recruits or prisoners, institutes of rural education and demonstration, reformatories for delinquent minors.

The Minister of Education drafts the bills for educational laws and prepares budgets to be presented to the Parliament; through decrees, regulations and directions, he determines and applies the Government educational policy and is responsible for the operation of the whole system. The Minister is assisted by the Under-Secretary, the administrative head of the Ministry, and by the Directors-General of Primary, Secondary, Industrial and Commercial Education, and of Libraries and Museums, all responsible to him and to the President.

The Directors-General, assisted by a staff of inspectors, visitors and other experts, supervise the institutions under their charge and submit to the Minister's decision the major technical and administrative matters—curricula, courses of study, methods of instruction, special regulations, examination system, etc.—and all the appointments and promotions.

Various laws, especially that of August 26, 1920 on compulsory attendance, impose on local authorities and, under certain conditions, on landowners and large industrial and mining enterprises, some responsibility in the support of elementary education. Although the Constitution of 1925 also provides for a certain degree of administrative decentralization, nevertheless, very little has yet been achieved in order to share the burden upon the State of the complete financial support of education, and the exclusive control of education by central authorities.

Public education is practically free. In

secondary schools and in the University extremely low fees are charged, and a great number of scholarships are granted to needy students at both levels. Elementary school children receive free school materials, and, in many of the poorest areas, breakfast, lunch and clothes.

Private institutions, except the Universidad de Concepción, the Universidad Técnica Federico Santa María (Valparaíso), a few secondary schools maintained by foreign groups and the elementary schools of the Sociedad de Instrucción Primaria, are Roman Catholic. Practically all of them charge registration fees, and receive some public financial support.

The school system consists of:

Primary level. 1. A few infant and kindergarten courses, mostly private.

2. About 4,000 primary schools, divided into three classes: (a) six-year schools, to which a vocational grade or a shop school is usually added (12 per cent of the total number); (b) four-year schools (16 per cent); (c) two- or three-year schools—usually rural, one-teacher schools (72 per cent). Specifically rural schools are beginning to develop, as well as adult education.

3. Primary preparatory schools, attached to the Liceos, which are actually selective on a social class basis.

4. Schools for physically handicapped.

Secondary level. 5. Six-year *Liceos*, in which almost exclusively academic education is given, and the completion of which is prerequisite for entrance to university schools. A few *Liceos técnicos* have been created recently, in which vocational and academic education are combined.

6. Commercial, agricultural, industrial, mining, vocational feminine three- or six-year schools, in which, besides specific courses, some general education is given. Students who complete the courses in these schools may pursue more advanced work in other institutions.

7. Normal schools for elementary teachers.

8. Schools for artistic education.

University level. 9. Professional schools of the faculties of Law and Social Science, Biology and Medical Science, Mathematics and Physical Science, Philosophy and Education, Fine Arts, Economy and Business, Veterinary, and Agriculture. Professional diplo-

CHILE, EDUCATION IN

mas granted by the University of Concepción and the Catholic University are controlled by the University of Chile. University extension, summer and winter courses have been offered regularly since 1936.

The following figures (for 1939, when the population of Chile was 5 million) and the comments give an idea of the relative importance of these different types of schools and of the distribution of educational opportunities:

Type of school	Total average attendance	Per cent of attendance in private schools
Infant and Kindergarten courses	3,000*	60 per cent*
Elementary schools ..	445,125	17
Vocational grades and shops	12,858	9
Preparatory schools (attached to Liceos)	33,327	63
Liceos	39,575	37
Agriculture, mining, industrial schools ...	5,092	35
Commercial schools ..	5,662	25
Vocational feminine schools	3,801	6
Normal schools	1,672	11
Artistic education schools	1,412	20
University schools ...	6,595	30

*Estimated.

Illiteracy among those over seven years of age has been reduced from 80 per cent in 1850, 60 per cent in 1900, to 20 per cent in 1940. However, only 7 per cent of the pupils who enter elementary school complete the six-year course. About 70 per cent of the population of elementary school age and about 12 per cent of the population of secondary school age have some educational opportunity.

Mainly because of the traditional prejudice against manual work, which still subsists in the upper strata of society, only 20 per cent of the secondary level population is engaged in vocational studies. About 80 per cent of the pupils who enter the Liceo come from the preparatory elementary schools. Private schools at all levels select their pupils on an economic and social class basis.

In spite of the great progress of social, economic and political democracy during the last two decades, these figures and remarks support the statement that Chilean education still reflects the sharp class division typical of Chilean society. In fact, although not legally, three systems may be distinguished,

with growing relationships between them, especially between the first two: public elementary schools and vocational courses—for the masses; public preparatory schools, liceos and higher education—for the middle classes; private preparatory schools, liceos and higher education—for the upper classes.

Elementary school teachers are prepared in six-year boarding normal schools. Courses for teachers in service, school principals, supervisors and visitors are regularly held at the Superior Normal School, Santiago.

Secondary teachers are prepared in five-year courses at the Instituto Superior de Humanidades, Instituto de Educación Física y Técnica and Instituto Pedagógico, of the Faculty of Philosophy and Education. Summer and winter university courses provide opportunity for post-graduate students. Demonstration schools are connected with the institutions for teacher education.

Because of their different educational qualifications and of prevalent ideas about the matter, elementary and secondary teachers have different salary scales. Both are entitled to quinquennial increases of 20 per cent, so that initial salaries are doubled in 25 years. They can retire on full salary after 30 and 35 years, respectively. They also enjoy the manifold benefits of the Security Fund for Public Employees, and a degree of professional and economic security which can hardly be found in other countries.

Secondary schools and universities attract an important number of students from other Latin American countries. Chilean educators have contributed to the reorganization of educational systems in Bolivia, Venezuela, Santo Domingo, and Costa Rica.

From the point of view of educational theory and practice, Chilean education is undergoing a slow, but profound, process of transformation. The tendency to abandon the old traditional and authoritarian pattern and its rigid uniformity, in order to secure a better adaptation to individual differences and to the social and economic needs of national life, is particularly noticeable in elementary education. Experimental elementary schools, and the Liceo Experimental Manuel de Salas have been organized in order to try new educational theories. A commission has recently been appointed to make a survey of Chilean education. Its reports should furnish a sound

basis for future reforms of the whole system.

CHINA, EDUCATION IN. Education in China is as old as Chinese civilization, but the introduction of modern schools is a comparatively recent development. The first system of modern schools was set up in 1902. In 1912, with the establishment of the Republic, there was introduced a new system which bore some resemblance to the American system. A revision in 1922 provided for two levels of secondary education similar to the junior and senior high schools of the United States. While important changes have been made since then, the system today still follows the main outline adopted in 1922.

The School System. The six-year elementary school is divided into a four-year lower primary school and a two-year higher primary. After the elementary school, one may enter the three-year junior middle school or the junior vocational school, which usually provides for a three-year course. Upon graduation from the junior middle school, one may enter the senior middle school, the normal school, or the senior vocational school. The senior middle school, offering a three-year course, leads to the four-year college or university or to technical or professional schools.

Aims of Education. The program of education is planned in harmony with the spirit and purposes of *San Min Chu I*, the guiding principles of new China since the inauguration of the present government in 1928. The aims of education, as officially stated, are "to enrich the life of the people, to maintain and develop social life, to promote the livelihood of the citizens, and to continue and foster national life, in accordance with the spirit of *San Min Chu I*, ultimately aspiring to the independence of the nation, the assertion of people's rights, the development of people's livelihood, and the realization of universal peace and brotherhood."

Educational Administration. Prior to the establishment of the present regime, the government followed a laissez-faire policy in education. There was no co-ordination of educational effort, no supervision over any private schools. Schools and colleges grew without reference to the considered needs of the locality; standards were varied and often very low. Since 1928, the central government has adopted a more positive policy with the purpose of building up a national system of schools closely articulated to the needs of the nation. To achieve this end, a centralized system of educational administration was inaugurated. At the head of the national system stands the Ministry of Education, whose chief authority is the Minister of Education, appointed by the National Government at the recommendation of the President of the Executive *Yuan*, of which the Ministry is a branch. The Minister of Education exercises control and supervision over all branches and levels of education in the nation; he is assisted by vice ministers, secretaries, inspectors, and clerks. Besides recommending to the National Government educational laws which determine major policies, he issues ministerial orders and regulations which must be obeyed throughout the nation. The Ministry is divided into five departments: higher education, general education (elementary and secondary), social education, Mongolian and Tibetan education, and general affairs. There is a Bureau of Compilation and Translation in charge of the examination, translation, and publication of school books, and a number of committees such as the Committee on Medical Education, the National Committee on Compulsory Education, the Committee on Cinema and Radio, the Committee on Moral Training of Youth, the Committee on Physical Training, etc.

The highest educational office within the province is the Department of Education. The Commissioner, who is a member of the Provincial Government, is appointed by the National Government and is responsible to the Minister of Education. Although he is charged with the execution of national laws and ministerial orders, he has a good deal of authority and has occasion to exercise much initiative within the province. Provinces are divided into *hsien* and municipalities; in each there is a Bureau of Education, with a Direc-

tor, assisted by a small staff, and responsible to the Commissioner of Education of the province.

Elementary Education. The elementary school admits pupils at the age of six. Its curriculum consists of civics, hygiene, physical education, Chinese language, social studies, nature studies, arithmetic, manual work, art, and music. Elementary education is free. The law recognizes 6-12 as school age and four years of primary education as the minimum of compulsory education. While the principle of universal compulsory education has been accepted for many years, the realization of the ideal has been frustrated by practical difficulties, chief of which is the financial cost of providing facilities for schooling. Several plans previously adopted proved to be merely paper plans. In 1932, the Ministry of Education took steps to initiate a more workable plan with a definite program of financial subsidies from the national government to the different provinces. The latest plan, adopted in 1935, provided for three stages for the achievement of universal compulsory education. The first stage, 1935-40, called for the establishment of enough schools and classes to give one year of primary education to 40 per cent of the nation's children of school age; the second stage, 1940-45, was to bring two years of primary education to 80 per cent of children of school age; and finally the third stage, 1945-50, was to extend universal education to four years for all children of school age. That the plan was really workable in the light of actual conditions was proved by the notable progress made in the first two years of the plan. The year 1935-36 saw the establishment of 35,175 primary schools and 25,901 part-time schools which provided instruction for 3,841,930 pupils hitherto neglected. The next year, 1936-37, witnessed the increase of 13,267 primary schools and 38,117 part-time schools and brought primary education within the reach of 4,405,291 additional pupils. These increases raised the total enrollment to 21,435,353, which constituted approximately 43 per cent of the total population of school age. If it had not been for the outbreak of the war, the plan would most probably have proceeded in accordance with the original schedule.

Secondary Education. There are three types of secondary schools: the middle school,

the normal school, and the vocational school. The junior middle school and the senior middle school may be established separately or combined into one institution. The curriculum of the junior middle school consists of civics, Chinese, English, history, geography, mathematics, physics, chemistry, zoology, botany, hygiene, drawing, music, manual work, physical education, and scout work. These studies are continued in the senior high school, with the addition of logic, with the differentiation of Chinese and foreign history and of Chinese and foreign geography, and with military training (for boys) or first-aid (for girls) taking the place of scout work. All subjects must conform to the standards promulgated by the Ministry of Education; there are no electives in the middle school curriculum. Physical education is given much emphasis; the regulations stipulate that no classes should be scheduled after 3:00 p.m. so that students may spend two hours every afternoon in physical activities. Science is particularly stressed. In response to the needs of the nation, and also to offset the traditional neglect of science studies, great effort is being made to promote the study and teaching of science in middle schools and colleges. It was found that science teaching in the middle school was handicapped by the lack of competent teachers, of adequate textbooks, and of laboratory equipment. To overcome these difficulties, summer institutes for teachers have been inaugurated; colleges and universities are charged with the urgent task of producing more science teachers; textbooks are being prepared by the Bureau of Compilation and Translation and by scholars under the encouragement of the Ministry of Education; universities and research institutes have been asked to construct laboratory apparatus with homemade materials to make them available at low cost; and joint laboratories have been established to enable adjacent schools to make common use of the facilities at different hours.

The normal school admits graduates of the junior middle school (or students of equivalent standing) for a three-year course which qualifies for elementary school teaching. Its curriculum is standardized by the Ministry of Education. The principle is maintained that all normal education should be under government support and control. Tuition is free; in

many cases, free board is also provided. To meet the urgent demand for primary teachers, a short course is offered in abbreviated normal schools which admit graduates of elementary schools for a four-year course; and some normal schools establish a special one-year course for graduates of the senior middle school or the senior vocational school.

Vocational schools are of two types: the junior vocational school, which admits elementary school graduates for a three-year course, and the senior vocational school, which provides a three-year course for graduates of the junior middle school or a six-year (sometimes five-year) course for elementary school graduates. Great emphasis is laid on practical work, to which the students are supposed to devote approximately half of their time. The official regulations require that vocational schools must be equipped with shops, factories, and experimental farm stations, or provide for such practical work in cooperation with farms, factories, and business firms in the community. There is no tuition as a rule, but a small fee is permissible.

Mention must be made of two important policies of the Ministry in regard to secondary education. The first is the maintenance of a high standard of academic achievement, not only in science but in all studies. The former *laissez-faire* policy had permitted the appearance of numerous secondary schools, a third of which were under private control and management, with varying standards, often very low. Since 1932, the Ministry has set definite standards in curriculum, in budget, in equipment, etc. to which all schools must conform. Moreover, official graduation examinations have been instituted for middle schools and normal schools to insure that the standards are attained.

A second policy is to discourage the increase of middle schools and to stimulate the growth of normal schools and vocational schools. Finding a condition of uneven development in which middle schools constituted 70 per cent of all secondary schools, normal schools 20 per cent, and vocational schools only 10 per cent, the Ministry ordered in 1933 that provincial and municipal budgets must be so apportioned that 40 per cent of the funds should be spent on middle schools, 25 per cent on normal schools, and 35 per

cent on vocational schools. Furthermore, national subsidies are given to assist the growth of vocational schools.

Higher Education. There are three types of institutions of higher learning: the college, the university, and the technical school. The college course consists of four years; a university contains three or more colleges, one of which must be science, pure or applied; and technical schools provide specialized courses of two or more years. In higher education, the emphasis is on quality rather than on quantity. While there is recognition of the great need of a more even geographical distribution of higher institutions in order to bring more equal opportunity to different parts of the nation, it is maintained that the most urgent problem is the improvement of quality rather than the increase of more institutions. After several years of drafting and revision, standards of college curricula have now been promulgated by the Ministry. Minimum standards of budget and equipment have been in effect for some years. Effort is now being made to institute uniform entrance examinations and graduation examinations conducted by the government for all colleges and universities.

The promotion of science is a major policy in higher education. Private as well as public colleges and universities are given special grants to develop their science departments. Administrative measures have been adopted to restrict enrollment in non-science departments and to encourage more students to take up the study of technology, science, agriculture, and related fields. As a result, the proportion of students enrolled in science departments has increased noticeably in recent years. While in 1929 it was found that the science students constituted only 26.9 per cent of the total enrollment of higher institutions, the percentage rose consistently every year since then until it reached 44.4 per cent in 1936; and among new students admitted in 1939, 59.4 per cent were registered in the science departments.

Space permits only a brief mention of the new attention given to the preparation of secondary school teachers. The latest development is the establishment of higher normal colleges, either independently or in connection with national universities. The normal college offers a five-year course which pro-

vides for a proper balance between the knowledge of teaching subjects and the knowledge of education and psychology. With free tuition, free board and lodging, it is hoped that the program will draw more talented young people into the teaching profession.

There were 108 institutions of higher learning on the eve of the war in 1937. The destruction of these institutions and their stubborn determination to carry on under adverse circumstances have now become an epic story. Of the 108 institutions, 91 were directly affected by the war: 25 were forced to close down, 14 suffered complete destruction of their buildings, 15 were victims of air bombing, and 37 had to move to new quarters.

While some institutions had foreseen the danger and had made preliminary arrangements to establish new quarters and to remove a part of the most valuable equipment, others did not contemplate removal to new quarters until the invaders were virtually at the door. In the latter cases, the migration to new quarters often consisted of no more than a determined band of faculty and students who set out on foot without definite knowledge of what the future had in store for them and who had to travel in scattered groups and under disguise to avoid the interception of the invaders. The migration of some institutions from the coast to Szechwan covered a distance of 1,000 to 2,000 miles by devious routes, partly by train, partly by boat, partly by trucks, and partly by foot.

By the end of December, 1939, it was estimated that the losses sustained by institutions of higher learning had amounted to more than ninety million dollars. Yet, despite these heavy losses, the Ministry of Education reported at the end of 1940 that 113 higher institutions were carrying on actively and had enrolled for that year 44,422 students as compared with 31,188 students in 108 institutions in 1937. Moreover, this growth has been accompanied by positive gains in the strength of institutions and in a more even geographical distribution of institutions in different sections of the country. For some years before the war, the Ministry of Education had been urging the amalgamation of smaller institutions into large and strong universities and the elimination of wasteful duplication and competition in a few large cities near the coast. Since the migration of

universities in wartime, universities have pooled their resources to form such strong institutions as the Northeast Joint University and the Southeast Joint University, each of which represents the combined strength of three or four independent universities. Furthermore, the migration has brought higher education to areas hitherto much neglected, and has gone far toward equalizing the opportunity for higher education in different parts of the country.

Adult Education. In a country with such a high percentage of illiteracy as China, the importance of adult education is obvious. Early experiments in adult education started at the time of the first World War, when James Y. C. Yen and other Y. M. C. A. secretaries organized literacy classes for Chinese laborers in France. The experiments were continued in China after the war under the auspices of the Y. M. C. A. until a National Association of Mass Education was organized in 1923. In later years, the movement turned more and more in the direction of rural reconstruction and the improvement of daily living.

In the meantime important language reforms greatly aided the progress of mass education. Under the leadership of Professor H. C. Chen and other scholars at the Southeastern University in Nanking, an effort was made to determine the most commonly used characters of the Chinese language. One thousand most useful characters were later chosen to be the basis of instruction in literacy classes. The introduction of a system of phonetic symbols made it easier to teach a uniform pronunciation of the characters and gave impetus to the unification of the spoken language throughout the nation. Most important of all was the "literary revolution" initiated by Dr. Hu Shih (now known as the Father of the "Chinese Renaissance") and others, which unified the spoken and the written forms of the language and produced a new literature more accessible to the common man.

In recent years, the National Government and the provincial authorities have paid increasing attention to adult education. Various agencies are employed for the liquidation of illiteracy and the spreading of information for the betterment of daily living. Much is heard in China today of social education,

which refers to a wide range of educational agencies, such as the museum, the library, the cinema, the radio, the drama, the public athletic ground, the adult school, evening classes, etc. The methods of social education are not stereotyped; numerous experiments are being carried on to find out the best means of reaching the common people of the towns and villages. Traveling libraries, schools on wheels, traveling student troupes combining entertainment with instruction, mass singing: these are among some of the means found to be effective in meeting the needs of the masses whom the elementary and higher schools have not reached.

A comprehensive plan was adopted in 1940 for the promotion of adult education through citizen schools. The plan looked forward to the obliteration of adult illiteracy within five years by gradual stages. In the first two years, a citizen school was to be established in every three *pao*, which is a unit of political organization consisting of ten to fifteen families. The goal was to have a citizen school in every two *pao* in the third and fourth years and one in each *pao* in the fifth year, hoping thus to have enough schools by the end of 1944 to reach the entire illiterate population. Progress in this plan has been uneven in different provinces, but the report of the first year showed a number of provinces able to keep up with the schedule, while some localities have even exceeded the mark set by the five-year-plan.

War-Time Policies. The war in China is known as the twofold task of "resistance and reconstruction." In the reconstruction program, education naturally occupies an important place. Great effort is being made to enforce universal compulsory education and to improve the quality of education in the secondary and higher schools. Technical education and scientific research are given a more prominent place than ever, equal emphasis being laid on agricultural and industrial needs. At the same time, there is a growing recognition of the importance of the social studies as a means of reëvaluating the traditional Chinese culture and the new ideas that have come from the West.

In the schools, the guidance of youth is given closer attention. Measures are introduced to promote close personal relations between teachers and students. A form of extra-

curricular tutorial system is now required in all schools and colleges. Moral training and physical training are two phases which are much stressed.

CHOATE FELLOWSHIPS—See SCHOLARSHIPS AND FELLOWSHIPS, INTERNATIONAL.

CHORAL SPEAKING. Choral speaking is the recitation of poetry or rhythmic prose by a group of individuals. It is a form of artistic expression traceable to the dramas of classical Greece. The chorus was used by the various Greek dramatists to provide narrative, to heighten emotional effects, and to interpret chants, lamentations, and incantations. Euripides' *The Trojan Women* is a good example of a classic play that employs choral and antiphonal speaking with artistic effects. Modern plays that likewise make use of choral speaking include T. S. Eliot's *Murder in the Cathedral*, and the *Scenes and Plays*, written expressly for choric interpretation, by Dr. Gordon Bottomley. While unison or refrain speaking has been used in the theatre and the church for ages, choral speaking as a means of interpreting literature is of rather recent advent.

The modern interest in choral speaking is said to have been crystallized in 1922 at Glasgow, Scotland, where Marjorie Gullan founded the first verse-speaking choir with the encouragement of the poet laureate, John Macfie. Since then the movement has spread throughout Europe, South Africa, and America. It is now an accepted method of teaching poetry in many elementary and secondary schools, and representative colleges and universities offer courses in Choral Speaking and The Teaching of Choral Speaking.

Choral speaking has been received enthusiastically by many educators who attribute to it social, psychological, cultural, and vocational values. Speech educators use choral speaking as (1) a technique to improve the voice and articulation of their students, (2)

a means of teaching the oral interpretation of literature, (3) an extra-curricular activity for interested students.

The members of the verse-speaking chorus are usually grouped according to voice quality. *Light*, *medium*, and *dark* are terms that have been adopted to describe the three main kinds of voices. These terms roughly coincide with the *soprano-tenor*, *mezzo-baritone*, and *alto-bass* categories of the singing voice. If the group is large—fifteen or more members—it is customary for a leader (usually the teacher) to conduct the group. After the selection has been decided upon, the meaning and interpretation are discussed and the lines are assigned to individuals, groups, and the entire chorus. Thus, whether the selection is a Mother Goose Rhyme rendered by a chorus of kindergarten children, or a sustained poem like Vachel Lindsay's *The Congo* interpreted by adults, a variety of effects may be obtained. CHOREA. Chorea, commonly called St. Vitus's dance, is a disease in which the most prominent symptoms are involuntary grimaces; jerky, twitching movements of the body; and emotional instability. Motor co-ordination is impaired and the child stumbles, often falls, drops things, and has difficulty feeding himself. He cries easily, is cross and irritable. Schoolwork is, of course, affected because thinking is disorganized and there is difficulty in remembering.

Chorea is usually regarded as a manifestation of a rheumatic infection and is commonly associated with tonsillitis, arthritis, and endocarditis. It is most prevalent between the ages of five and fifteen, affecting girls more frequently than boys. Treatment consists primarily of rest and seclusion. F.K.M.

CINCINNATI PLAN. To the late Dean Herman Schneider of the University of Cin-

cinati goes the honor of establishing and developing co-operative education at the college level in the United States. Dean Schneider would have been the last person to claim that the basic concept of cooperative education was entirely original with him. Students of industrial history are aware of similarities between the Fellenberg movement in Switzerland (and its offshoot, the manual labor movement as organized in the United States in 1820 by Joseph Neef and William McClure) and cooperative education as developed at Cincinnati and elsewhere.

The Cincinnati plan, also called the Schneider plan, provides for completing college requirements by a combination of work experiences off the campus and instruction on the campus. Instead of giving shop training to engineering students on the campus, the students are trained under actual employment conditions. The student is paid for his off-campus work, which is carefully selected to fit into the curriculum requirements. (See ANTIOCH PLAN; COOPERATIVE EDUCATION.) F.T.S.

CITIZENSHIP, EDUCATION FOR (Civic Education). Education for effective citizenship is one of the most widely accepted goals of public education. It is recognized as vital for the continuance of the democratic way of life, although there is no agreement as to the best method of developing social competence. Practice varies all the way from aiming at democratic goals under firm administrative direction to allowing considerable personal choice to pupils in planning their curriculum and activities.

"The school is the outstanding agency in civic instruction, but it is closely related to other instrumentalities of political education such as governmental agencies . . . political parties, special patriotic organizations . . ."² Especially after World War I there was much alarm at the lack of citizenship training in isolated communities and among foreign-born groups. Various organizations such as the American Legion have sponsored adult programs in the effort to remedy this situation.

The founders of the American republic championed education as basic to the welfare

of the state. The compulsory school attendance laws of the states have been instituted for the primary purpose of assuring a literate citizenry. But civics as a school subject was fairly slow to develop. The great influx of immigrants in the nineteenth century made some instruction in the American form of government especially desirable, but it was not until well after the Civil War that even a minority of schools began to offer courses in *civil government*. The report of the Madison Conference of 1892 indicated that about one-sixth of the elementary and one-third of the high schools offered such courses. The recommendation was made that American history and civil government be taught in the last years of the elementary and of the high school. Subsequent committee recommendations and influence by non-school agencies and state laws in time resulted in practically universal offering of civics, which is now a recognized part of the social studies (*q.v.*). Civics as a school subject is at present customarily offered at the ninth grade as "community problems"; and at the twelfth grade as a separate half-year course in government, or as part of a "Problems of Democracy" course.

The early teaching of civics was usually a formalized textbook approach, frequently consisting of requiring pupils to commit the Constitution to memory. Even in later improved form it stressed the structure and machinery of government rather than its function, with little relation to the individual citizen. After 1900 the emphasis shifted from the Constitution to the citizen, and the introduction of *community civics* tended to provide a more realistic approach.

No graduated scheme of citizenship training has yet been devised. There is, however, a general recognition of the sequence of training elements from the simple recognition of symbols to the highest appreciation of the ideals of America. In the primary grades stress is placed upon the flag, creeds, patriotic songs, and simple projects of national and community service. These symbolic forms are also studied in the middle grades and are given theoretical bases in some geographic elements and in the stories of the exploits of national heroes. In the junior high schools much attention is given to American history and community projects and

studies. Formal civics is a fairly standardized study for grade nine. In the senior high school the students generally study American government and through another course in United States history and problems of democracy they secure a better historical basis for citizenship. International cooperation, fundamental rights, civic duties, concepts of democracy, and the problems of a highly integrated society are stressed and explained. At this level many classes render community services and carry on national political conventions, mock courts, peace conferences, student government conventions, and other forms of activity designed to prepare them for adult political participation.

Administrators and classroom teachers have also shown considerable resourcefulness in devising experiences outside of the regular course content designed to promote training in democratic living. In the elementary school the child is introduced to the ideas of cooperation and interdependence as they operate in his school, his family, and his community. He may observe the activities of the school clerk and the janitor to learn that these individuals make a real and necessary contribution to the life of the school. The post office, police station, and fire house are frequently visited so that the child may learn how necessary each is in contributing to group living. Through these means the child very early becomes aware of the relationships, the responsibilities, and the privileges of life in a democratic society. He learns to take proper care of school equipment, respect the rights of his comrades in play and in conversation, "take his turn," and develop socially sanctioned manners. Thus the fact is increasingly emphasized that any service is important and that the participation of each person according to his abilities is essential to effective democratic living.

The increased maturity of children in the intermediate grades permits the introduction of more highly organized forms of participation. Children have nearly always been invited to help with routine activities as a help to the teacher, but the relationship upon which this depended was usually confined to the direct one between teacher and individual pupil. The organization of classroom committees, clubs, and councils enabled the children through their own organizations to

assist with both minor and major school problems. Room committees usually assist with such responsibilities as keeping the room and display materials in good order, distributing and collecting materials, keeping a bulletin board up to date and attractive, checking attendance, and similar routine activities. Clubs and councils frequently give valuable assistance with such larger concerns of the school as safety, health, maintenance, and community contact. In this way a sense of individual and group responsibility may be evolved, along with the skills of social cooperation and adjustment. Through cooperative planning, involving practice in the democratic procedure of discussion, acceptance of majority decisions, and cooperative execution of projects, the pupils also learn to develop the qualities that make for leadership and cooperative endeavor in all aspects of group living. (See CLUBS, SCHOOL; SELF-GOVERNMENT; STUDENT COUNCIL.)

Opportunities for democratic practice in considerable number are provided on the high school level. Innumerable examples of learning opportunities in out-of-class and community relationships have been related in a survey of ninety representative secondary schools.¹ In some of the schools surveyed, pupil conduct was controlled through group regulation and enforcement. Committees appointed through the student councils frequently took charge of all the details of formulating regulations; policing halls, assemblies, and activities; and bringing offenders to trial. In other schools, individuals were placed on their own responsibility within a framework of group spirit developed through conscious effort on the part of all pupils. Some schools utilized student help widely in management and care of equipment, grounds, and such services as cafeterias and libraries. Many examples were found of student organizations to guide and advise new students. Realism in civic education was increased in many centers by relating the school to the community through surveys, campaigns for local improvements, and cooperation with various civic and social agencies. Students thus learned directly that citizenship requires personal service. The case book¹ says of these activities (p. 192): "These are the laboratories of democratic living. Here boys and girls have opportuni-

ties to learn through practice the lessons of shared planning, group deliberation, action for the general welfare, and personal responsibility, which are the stuff of the democratic fabric."

The war has provided the schools with further opportunities for training in cooperation with the national welfare. Many high schools have Victory Corps which carry out a highly organized program of student help and participation. Both elementary and secondary school children take part in scrap metal drives and civilian defense activities. Out-of-class as well as class activities are keynoted with the desire to make pupils conscious of the advantages of democracy and a determination to demonstrate its efficiency.

Citizenship training as given in the school is still criticized, however, as unrealistic and impractical. The schools seldom give attention to the history of institutions other than the state, and democracy as a social process receives scant notice. Most textbooks have narrowly identified democracy with the extension of suffrage alone. The report of the Regents Inquiry in New York State revealed a disturbing picture of poorly informed and uninterested high school pupils who were negligent in discharging the simplest civic duty.⁴ The fact that in the country at large fewer than 40 per cent of the voters cast ballots in the election of November, 1942, the first congressional election after the United States became embroiled in World War II, revealed an apathy which is a serious reflection upon all agencies of civic training, both within and without the school.

There are some hopeful prospects, however. The Educational Policies Commission (*q.v.*) survey¹ revealed many promising practices involving cooperative planning and execution of socially useful jobs with widely shared responsibility. It revealed conclusively that in spite of differences in concept and approach, administrators, teachers, students, and citizens in every instance which was described sincerely wanted to make democracy work and believed that education was a powerful instrument for that purpose. Among demands stimulated by the war for changes in the program to meet the crisis there appeared an eloquent plea for a reorganization of the curriculum so that every high school and college student would devote two hours a day

five days a week to a discussion of problems of world significance and a close study of current history. This volume proposed twelve specific units and furnished lists of supplementary readings and other materials (Meyer, Walter E. and Coss, Clay, *Education for Democratic Survival*, Washington, D. C.: Civic Education Service, 1942). The complexity of the many and intricate problems on which the rank and file of American citizens will have to pass judgment makes it imperative that in their formative years citizens may acquire a common body of facts, understandings, loyalties, and skills. If democracy is to survive, civic education must keep pace with mechanical and military advances.

The schools have recognized that we have failed to impress newly arrived citizens with the significance of their new status. Some approach to the Ephebic Oath taken by Athenian youth is achieved by the citizenship day ceremonies at Manitowoc, Wisconsin. Many schools encourage student participation in school government (See publications of National Self Government Committee, 80 Broadway, New York City). Some schools award a rating for "citizenship" apart from marks for specific subjects, and this factor is frequently taken into consideration in nominations for honor societies or awards at commencement. The best school practices recognize that effective training for citizenship should provide for a broad-gauged concept of democracy, social and economic as well as political, and should instill lasting devotion to the principle of cooperative action for the common good. (See AMERICANIZATION; SELF GOVERNMENT; SOCIAL STUDIES, TEACHING OF.) E.B.W. and H.T.M.

CIVILIAN CONSERVATION CORPS, EDUCATIONAL WORK OF. Conceived as an emergency relief measure for unemployed youth in the depth of the depression, the Civilian Conservation Corps (hereinafter called the CCC) was established in 1933. It was abolished by Congress in 1942, as the demands for youth in the armed services and in wartime industries eliminated most of the youthful unemployed of the nation. In its peak year, 1935-36, it enrolled 459,000 youths and expended \$490,109,000, of which \$102,391,000 was paid to enrollees. The CCC was originally patterned somewhat after work camps organized for youth in certain of the European countries, notably England and Germany.

While the entire plan of the CCC was in a sense designed to be broadly educative, the organized features of an educational program in the camps were delayed for several months after their initial organization. As the need for filling constructively the unused evenings and leisure time of the enrollees became more evident, plans were inaugurated for definite instruction, and an organized program of education and recreation was started in May, 1933. The primary step was taken in this phase of the program through adding a staff member to most camps as "Educational Director". The first of these were selected and assigned to camps in February, 1934. While directly responsible to the Army officer in charge of the camp, the Educational Director served also under the direction of a district adviser and a Corps Area Adviser.

The educational task within a camp called for ingenuity, resourcefulness, leadership, and persistence in conducting a pioneer educational task under difficult circumstances. The type and value of the educational program in each camp varied somewhat proportionately in the degree to which the director possessed these qualities and the extent to which he could secure and inspire the cooperation of the men with whom he worked.

In many camps, uniquely successful programs of broad education, built upon the wishes and the needs of the individual en-

rollees, were carried forward. Classes in varied fields ranging from informal groups studying problems growing out of their daily work in forestry, soil conservation, motor mechanics and the like, to more academic courses in elementary skills, business subjects, and regular high school courses were taught in the camps or by correspondence study. In other camps, the educational program simmered down to a few classes, poorly attended, with a tendency to resort to compulsory attendance, and an indifferent attitude on the part of both boys and the camp officials.

In general, the educational program showed continued improvement as advisers and their associates in the camps experimented progressively with informal procedures, secured equipment and library facilities, and grew familiar with handling groups of young men with greatly varied interests and abilities.

If the CCC is revived, the results of this unique educational undertaking should prove of considerable value in planning more effectively the educational task in the camps. Probably the camp educational program could best serve the purpose of general physical conditioning combined with exploratory types of individual and class work and counseling, after which the enrollees could be sifted for technical, vocational, and other training into public and special schools better equipped to fulfill those special functions. CLAPAREDE, EDOUARD (1873-1940). The late Professor Claparède's personal history and his professional career were thoroughly harmonized so that his scientific and pedagogical work clearly reflected his basic personality characteristics. He is noted for a life-long perseverance against authoritarian dogmatism of any sort, in keeping with the spirit of his hardy refugee ancestors who, after the revocation of the Edict of Nantes, emigrated to the Suisse Romande from the French Midi. The Huguenot principles of liberal Protestantism vividly symbolized for him the principles and methods of free inquiry—and to these he dedicated all his professional and civic activities as physician, educator, psychologist, reformer, family man, and proud citizen of the city of Calvin and Rousseau. As a young interne, while working at the Salpêtrière, he was deeply aroused by the then acute Dreyfus affair which almost led him to spend more time on pro-Dreyfus debating than on his neurological studies. In the last decade of his life, he was to be similarly roused to an ardent stand against the principles and methods of Nazi Germany. Many a refugee student and scholar owes a debt of gratitude to this gently fearless Servetus of modern times. Some of his closest friends feel that the fall of France was directly responsible for precipitating his death.

Following in the footsteps of his distinguished relative, Flournoy the neurologist, Claparède early in 1904 took over the direction of the first independent psychological laboratory divorced from the faculty of philosophy. He continued with this work at the University of Geneva until his death. Earlier, in 1901, he founded jointly with Flournoy the well-known *Archives de Psychologie*. In 1912, with the assistance of Pierre Bovet, he established the famous Rousseau Institute, a teacher training institution which eventually was to become affiliated with the University of Geneva.

While he did distinguished work in many fields of psychology and also continued with part-time clinical practice in neuropsychiatry, Claparède felt that general psychology as a young experimental science needed to lean heavily on child psychology and educational psychology—if the psychologist was to keep his feet on the ground. Continuous contacts with children in the laboratory and in class-

rooms were to provide psychologists with what the physician can learn about human motivation through clinical patients. Psychology and child education were fundamentally inseparable fields of study for him. One cannot "teach" children without the help of a sturdy, realistic child psychology. These thoughts were eloquently expressed in his famous *Psychologie de l'enfant et pédagogie expérimentale*, published in 1909 and translated into ten languages.

Of his own research efforts, his findings on the prior appearance in children of the ability to distinguish differences before they are aware of similarities, in the face of seemingly contrary behavior of children in actual problem-solving activities, are of direct relevance to educators and educational psychologists. These and other studies on childish perception and selective attention had a direct influence on the whole series of investigations by Piaget (*q.v.*) and his collaborators, and on the work of Rey and other child psychologists.

The Rousseau Institute is the living embodiment of Claparède's most significant achievements. Basically a normal school, specializing in the pedagogy of preschool, kindergarten, and grade school children, it has been from the first an outstanding center of child research. It includes the well-known *Maison des petits*, a progressive, experimental nursery school and kindergarten. Students at the Rousseau Institute have an opportunity for field research and practice in several demonstration grade schools affiliated with the Institute. Numerous studies in child and educational psychology were published from it in the *Collection d'actualités pédagogiques*, published under the joint auspices of the Institute and the *Société belge de pédotechnie*, and in the *Cahiers de pédagogie expérimentale et de psychologie de l'enfant*. At the Institute, Claparède gathered and inspired a noted group of fellow investigators, students and teachers, including Descoeudres, Bovet, Piaget, Baudouin, Antipoff, Loosli-Usteri, Rey, and Meili. It is from this seat of his true labors of love that he diffused his influence in the field of progressive education—an influence exerted upon a great number of undergraduate and graduate students, practicing and prospective educators from Europe, the Near East, and North and South America.

In keeping with certain principles of Pestalozzi, Montessori and Dewey (*qq.v.*), Claparède emphasized and supported progressive teaching methods possible chiefly in activity schools. It was in ever improving activity schools that he saw real possibilities for increasing collaboration between a truly experimental pedagogy and a realistic child psychology.

CLASS INTERVAL (STATISTICS)— See FREQUENCY DISTRIBUTION.

CLASS MANAGEMENT. Good class management provides a social and material environment favorable to efficient and stimulating teaching and learning. It provides the clean, orderly, comfortable, and stimulating atmosphere in which the real business of the class—productive learning—can thrive. The problem is not only how to achieve this positive environment but how to do so without setting it up as the major criterion for evaluating classroom activities and making it of such moment that it rivals productive learning activity in its demands on time and attention. The painter needs a good light, a well-constructed easel, paints of the correct consistency, and brushes that won't shed, yet he could do little painting if he had to fuss and bother continually with these things. Similarly, the correct regulation of air, heat, and light; proper seating; care and distribution of supplies; selection and use of decorations; and the efficient use of class time are all indispensable to learning, provided they are given their proper auxiliary place in the classroom pattern.

Cleanliness: The custodian and his staff are responsible for the cleanliness of the classroom when the bell rings for the first morning class. Thereafter, until dismissal

time when the mop and broom again come into play, the cleanliness of the classroom is the concern of those who use it. Part of the teachers' (and parents') task is to develop in children the habit of tidiness, of, for instance, discarding wastepaper in the proper receptacles rather than on the floor, in desk drawers, or behind radiators. The teacher can do much to encourage proper disposal of wastepaper by making it convenient to do so; baskets should be placed at easily accessible places in the room, and one should be placed at each exit so the student may discard his wastepaper as he leaves. The cleanliness and neatness of the classroom should be a student responsibility, and such tasks as keeping floors and blackboards clean might well be assigned and carried out by the students themselves throughout the school year. When the room is used by many classes during the day it should become the custom for each class to leave a clean uncluttered room for the next group. A school-wide tradition of cleanliness, once established as a classroom habit, will need little further attention.

Comfort: Many aspects of heating, light, and ventilation are beyond the teachers' control. If the construction of the building has been so ill-adapted to the purposes for which it was built that no satisfactory scheme of ventilation is possible, and if the provision for artificial and natural lighting is inadequate, then the teacher cannot create ideal physical conditions. On the other hand, he can do much to make the physical conditions measure up to the fullest potentialities of classroom design and available equipment. (See BUILDINGS, SCHOOL; LIGHTING, SCHOOL.)

At least two major controls for room lighting are within the power of the teacher—the use of window shades to reduce or modify excessive or incorrect natural lighting, and the use of artificial lighting to supplement insufficient natural light. The following rules on lighting should be observed by the teacher: (1) Each student, when writing, drawing, reading, or otherwise engaged in seat work, should not have to contend with shadows on his working surface. It is to be remembered that the traditional light-over-the-left shoulder rule does not apply if the student is left-handed or when overhead lighting is possible. (2) Glare should be eliminated as far as possible. Sunlight shin-

ing directly on a working surface—a book, paper, or blackboard—is injurious to the eyes and decreases visibility. Judicious use of window shades can eliminate this problem. (3) Dull cloudy days generally do not provide enough natural light for the classroom; all shades should then be up and artificial lights used, particularly along the side of the room opposite the windows. (4) The teacher should not stand before a window during a class activity that requires the students to give him frequent attention. With the source of light behind the teacher, the children are forced to look directly into the light.

The optimum classroom temperature has been found to be between 67° and 73°, with a humidity slightly below 50 per cent. In some modern schools temperature, humidity, and air movement can be controlled by mechanical means. Where this is not the case, the teacher should keep on hand a reliable thermometer so that windows may be opened or radiators turned off for a time if the temperature rises beyond advisable limits. The physical efficiency of the human body has decreased as much as 15 per cent at 75°, when 68° is accepted as the standard. Direct drafts should be avoided in ventilating a room. As the beginning of every class hour the teacher should check temperature, ventilation, and lighting. If this is done regularly the likelihood of poor light, bad air, or overheated rooms will be reduced to a minimum.

Order: The maintenance of classroom order is an exercise in cooperative social living. For this reason, it is educationally wise to encourage students to assume a large rôle in classroom administration, since it is but a step from classroom civics to community civics. Active student participation and responsibility are much better training for citizenship than is submission to teacher dictation and domination. Certain aspects of class management lend themselves particularly well to student responsibility. The care and distribution of supplies and the setting up of equipment, for instance, can well be entrusted to student committees. These committees are best rotated in personnel so that each child has the opportunity to take part sometime during the semester, or if that is not advisable, the assistants may be part of

CLASS MANAGEMENT

the slate of class officers elected by the class, to continue in office for a fixed period or for as long as they discharge their duties efficiently. The teacher can furnish the committee with a statement of needed equipment and supplies for each day and allow the members to work out the best scheme of distribution, collection, and storing.

The practice of courtesy is an important feature of social living in the classroom. Rules regarding the amount of conversation and movement permitted during an activity period, the ways to conduct an orderly discussion, the rotation of routine responsibilities, such as passing the basket, erasing the board, collecting papers, checking supplies, etc., are followed more satisfactorily if the students have had a hand in drawing up the regulations and in enforcing them. Such student participation in class management involves more time in its organization at the beginning of the term than does the method of teacher dictation, but it makes for the better training in social living and is likely to run more smoothly because its source of power and direction is within the student group. (See *DISCIPLINE*.)

Routinization of Activities: The fixed, mechanical aspects of classroom management are best routinized. Routine is desirable whenever the habit formed saves time and effort, conserves material, or lessens confusion. It may be needed to produce orderly procedure, or to promote children's health, or to insure safety in case of emergency. Such activities as the collecting and distributing of supplies, taking attendance, regulating ventilation, and lining up for fire drill may be routinized. On the other hand, routine should not be applied where variability or freedom of action and alertness of mind are needed. Teaching and guidance procedures should not be routinized. The teacher whose teaching procedures are so well routinized that the students know his explanations are followed invariably by a period of note taking, then by a question-and-answer recitation, and then by a short test can destroy interest and initiative and lower the effectiveness of learning. Learning at its best is a process of stimulating discovery; routinization of learning defeats that purpose.

Classroom Decorations: Decorations in classrooms include all features that add to

the appearance of the room. They give color to floor, walls, and ceiling, and include such common decorative and useful objects as window shades or Venetian blinds, small shelves for attractive articles, flower receptacles, and illustrative materials for display. Even such learning aids as charts and maps have decorative value. The wise selection and appropriate arrangement of ornamental materials contribute much to pleasant study surroundings.

Classroom decorations may serve educational as well as æsthetic purposes. When students know that it is their room rather than only the teacher's room, the decorating of the classroom becomes a socially useful project in applied art. The selection, mounting, and care of decorations should be a student responsibility, performed as much as possible by and for the students. This activity can give excellent training in æsthetic appreciation and cooperative effort, and can help motivate, enlarge, and enrich regular learning experiences of the classroom.

If pictures are selected with a view to their value as visual aids related to the work in which the students are engaging, and if they are placed at the child's eye level so they may be seen easily, they aid learning as well as add to the room's appearance. The old travel poster or the faded print of the muses ceases to fulfill educational or decorative purposes when it no longer has any function in class activities and has become as much a noncommittal part of the room as the plaster and the molding. Conversely, pictures of the Lake Country while the class is studying Wordsworth's poetry, photographs of scenes from a production of *The Merchant of Venice* when the play is being read, examples of student plans for a projected transportation exhibit—these serve a positive purpose, provided they do not linger on the walls or bulletin boards beyond their period of maximum usefulness.

When classroom decoration is seen from a functional point of view, it is usually temporary rather than permanent, reflecting the changes in student interests. Since the classroom is the children's living room for so much of the day, it should reflect the activities of its occupants. The appropriateness of classroom decorations depends, therefore, not on abstract criteria of beauty, but rather on

the interests and activities of the students who live there.

CLASS PERIOD: The length of time devoted daily by a grade group, or class of pupils, to instruction in a given subject-matter field is known as the *class period*. The length of the class period is determined by several factors: (1) the philosophy of education in which the school believes, (2) the physical and mental maturity of the pupils, (3) the physical facilities, such as size and number of rooms in the school, (4) the number of pupils to be housed in the school building, (5) the number of teachers available for instructional purposes, and (6) the requirements set by state departments of education and by regional associations.

In the elementary school the current practice is more and more toward breaking away from a definite time limit for pupils to spend daily in studying and reciting in each separate subject field. The trend is toward setting aside large blocks of time in which attention may be given to activities and interests in which content materials may be utilized from a number of traditionally considered subject-matter fields.

In the secondary school the trend described for the elementary school is less marked. The length of period for classes in the secondary school ranges from forty minutes to eighty minutes in some schools. In recent years the trend has been clearly in the direction of the lengthened period. Instead of having pupils study independently for a short period and then go to a classroom for class recitations, the lengthened period has become a period in which directed study and recitation are both included without any definite division of time for each purpose.

In college the period is usually fifty minutes in length for the academic subjects, such as English, Latin, French, history, etc. For laboratory subjects, such as chemistry, physics, physiology, biology, etc., the class period is often lengthened to twice the length (100 minutes) of the period for the academic subjects. This latter practice is also common with the subjects in the practical arts field, such as, industrial arts and home economics. (See PROGRAM, DAILY; and SCHEDULE, DAILY.) O.G.J.

CLASS SIZE. The number of pupils in a class unit administratively under the direct and continuous guidance of one teacher generally indicates the class size. The average class size in a school or a school system is distinguished from the pupil-teacher ratio in the sense that the latter often includes in its computation nonteaching personnel such as librarians, counselors, and grade advisers. Class size is one of the component factors of the service load (see TEACHER LOAD), with which it is sometimes erroneously made synonymous. Included in the service load are all the activities and conditions that require time, energy, and attention in the line of the teacher's professional duties and interests.

Though class size increased sharply after 1914 in both elementary and secondary schools, reaching the highest point in the early 1930's, recent years have witnessed a tendency toward decrease, which was temporarily interrupted by the effects of the depression. The high schools, however, reached the peak of class size about five years later than the elementary schools. According to one study published in 1940, cities of more than 2,500 population report that the average size of kindergarten classes was 30, elementary school classes 34, junior high school classes 33, and senior high school classes 30.

The determination of the established class size for schools or school systems usually has been affected most by the size of school enrollment and the financial status of the community. Increase or decrease in class size generally has gone hand in hand with increase or decrease in enrollment. Declining birth rate, decreased immigration, lack of employment opportunities in time of depression, shifts of population, and induction of pupils into the armed forces in time of war have each, therefore, affected class size. Some

states have influenced the size of classes through their policy of providing state aid on the basis of number of units, each consisting of what is considered a fair number of pupils assigned to one teacher. Indiana, for example, has defined the teacher-pupil group in the elementary school as one teacher for 35 pupils. For the high school the unit is one teacher for 25 pupils.

Accrediting (*q.v.*) associations have regulations on the size of classes. These regulations which govern schools accredited by one or another of the agencies have a tendency to influence practice in nonaccredited schools as well. There is, of course, closer agreement on the maximum size of classes than on the minimum size, which is influenced by the number of children available and by economic considerations. Generally, too, the higher the school level the smaller the class size becomes. Though the effect of traditional practice has tended to stabilize class size in schools and school systems, occasional periods of financial stress, nationwide or local, generally have been reflected in increased class size.

The results of research in the field of optimum class size necessary for good teaching have not received as much consideration in the determination of established class size as has any of the other factors. The period of greatest interest in the study of desirable class size was between 1920 and 1930. Although there have been more than 250 studies since 1900, only about 70 can be considered experimental in nature. Of these, about a third included controlled conditions. On the basis of the pupil outcomes measured, the findings do not yield results conclusively favorable to either small or large classes. These results have been used by some school administrators and budgetary officers to justify increased size of classes. Other schoolmen, however, have hesitated to do this for fear of overburdening the teacher and losing educational outcomes not so easily measurable.

To yield usable results, investigations of class size are now needed which do not have the typical failings of previous studies. Of these failings, one is the wide variation and overlapping in the definition of small and large classes; for example, the range of small classes in various studies was from 7 to 35.

Another is the limitation of criteria of educational efficiency to measurable effects on pupils' knowledge. Failure to compare large and small classes in situations where appropriate, characteristic teaching techniques customarily have been applied has weakened the strength of many conclusions. Research on desirable class size should be concerned with the specific elements of the child's social and physical growth as well as his growth in acquired knowledge and skill. In addition, it should measure the comparative effects of class sizes on the instructional situation in the classroom, and on the teacher's health and stability as well.

One controlled investigation, representative of a growing interest in this larger point of view, was reported in 1943 by the New York Society for the Experimental Study of Education. In one phase of this investigation the findings of a similar nationwide study reported by the Research Division of the National Education Association in 1939 were completely corroborated. Teachers considered 31 a reasonable average size for elementary school classes; ranked class size very high among the burdensome components of teaching load; and reported that essential professional activities, particularly those concerned with treatment of individual differences of children, received inadequate attention by teachers twice as often in large classes as in small. When tested under objective conditions, teachers of smaller classes knew more about their pupils' educational, health, and socio-economic status than did those of larger classes. Under uniform and objective conditions small class size situations were observed to yield greater use of individualized techniques, greater diversification of learning activities and modes of expression, more indication of individual enterprise, and greater evidence of desirable social outcomes and social control based on cooperation, mutual planning, and participation.

Among the many factors that must be considered in determining the number of pupils who may work to best advantage in a class group are: (1) the type of administrative organization; e.g., the Platoon School may handle, successfully, more pupils in one group than could be served with some other plan, (2) the homogeneity of the group with respect to mental ability and interests, (3) the

social maturity of the group, (4) the type and amount of equipment and supplies available for the pupils, (5) the ability and ingenuity of the teacher, and (6) the type of activity in which the class group is engaged; e.g., a larger group might be taught in type-writing than in a foods class.

CLASSICAL INVESTIGATION. *The Classical Investigation* was an exhaustive three year study of the status, objectives, content, and methods of Latin instruction in the United States. It was not a "round table" discussion as all previous studies had been, but an investigation which secured valid educational data through an extensive objective testing program and from the recommendations it gathered from thousands of successful and experienced teachers. The report answered, and greatly decreased, ill-founded criticism of Latin study. Where the criticism was valid, however, the report made recommendations to Latin teachers for improvement. The report received almost immediate acceptance by the progressive Latin teachers of the country, and it also furnished the pattern for most of the later important investigations of secondary education and its subjects.

The principal findings of the investigation were:

1. The aims of Latin secondary school instruction should be those which can be attained during the secondary school period.

2. The first two years' instruction should be reorganized to reduce the grammatical work not essential to reading Latin, to postpone the introduction of some of the essential grammatical principles to the second year, and to begin the reading of connected material earlier in the course.

3. Transfer of desirable habits, knowl-

edge, and skills is not automatic but should be consciously striven for, and content and method should be organized accordingly.

4. The traditional course should be modified to meet the newer objectives.

It is to be regretted that through lack of funds Part II of the report, giving all of the data of the objective studies, was never published. It is on file in the Library of Congress. (See **LATIN, TEACHING OF**, and **CLASSICS, EDUCATION IN**.)

CLASSICS, EDUCATION IN. To the Greeks civilization owes one of its greatest debts, for they emancipated the human mind from superstition and developed the ideals of individual freedom and democracy. In architecture, art, and literature their productions are among the world's masterpieces. Their writings have profoundly influenced almost all the world's best thinking, and our English and American literature is filled with references to them.

To the Romans, who also were imbued with ideals of individual liberty and who appreciated and copied the art and literature of the Greeks, we largely owe the transmission of this heritage to us. To them we owe our finest ideals of justice and administration. They provided the language of the Christian Church, of scientific and literary work, and of international intercourse, for fifteen hundred years. Their writings have profoundly influenced all modern writings.

It is difficult to gain a thorough insight into the workings of the minds of the Greeks and Romans except through the study of their works in the original languages. There will always be those who are not satisfied to derive their ideas of this civilization second-hand. They are its interpreters to the world at large.

The Greeks through their vivid imagination developed a beautiful mythology, which was preserved by the Romans. References to classical mythology pervade not only our best literature but even the pages of our daily newspapers.

Our language in its vocabulary is much more classical than Anglo-Saxon. Of the

17,000 most commonly used words in the English language, as contained in Thorndike's word list, 52% are of Latin origin and over 11% Greek. The real meaning of a well-written document is likely to be in the classically derived words it contains. The classics have long served as a rich storehouse from which most of our scientific, legal, and theological terms have been derived. A real feeling for the precise shades of meaning of these words can be secured best through a study of the classical languages in the original.

From the Renaissance until comparatively recent times the study of the two classical languages, and especially of Latin, formed the core of all higher education beyond the elementary level. As causes for this stress upon the ancient languages may be assigned first, the reverence with which the new humanism treated the rediscovered masterpieces of Greece and Rome; secondly, the essentially vocational nature of these languages in a society where higher education was reserved for those preparing themselves for such professions as medicine, the law, and the ministry, in all of which proficiency in Latin was essential to progress and success; thirdly, the long-continued use of Latin as an international means of communication in such fields as the sciences, philosophy, and diplomacy; and fourthly, the conservatism of a long-lived system of education. Even after Latin had ceased to be the *lingua franca* of the occidental world, it still retained its pre-eminence in education.

Only within the last seventy-five years has Latin, and with it Greek, given way to other branches of instruction in both the secondary schools and the colleges and universities of Europe and America. The major reasons for this change in relative popularity are probably twofold, both traceable to the democratization of the school and the corresponding increase in enrollment: first, the growing importance of vocational education in the high schools and colleges; and secondly, the growing number of fields considered essential for a liberal education. In addition, the premium laid by modern society upon the practical has put into disfavor those subjects the value of which is not immediately apparent, and has occasioned a rebellion against an educational philosophy based on ideals which had come to contradict those of the

general public.

Most American colleges no longer require a knowledge of Latin as a prerequisite to the granting of an A.B. degree; such knowledge remains a requirement only for graduate work in certain restricted fields. Greek has almost disappeared as a secondary-school subject.

Although the classicist is already well aware of the contributions which the continued study of the classics makes to the development of the secondary school and college student, the students themselves should also be helped to see the values they will obtain from such study. For the values of even an elementary study of Latin see the article on LATIN, TEACHING OF. These values apply in greater or lesser degree also to the study of Greek. For superior students with definite literary, historical, philosophical, or linguistic talent both languages are of exceeding value, in some cases essential. For the average high school or college student, Latin and Greek offer the same advantages as the modern foreign languages and with them form a group which constitutes an integral part of a meaningful liberal education. A brief course in the elements of the modern scientific vocabulary, which is formed largely of Latin and Greek components, is believed by many educators to be advisable for students of the sciences. Finally, since all who regard themselves as educated must know and understand the traditions of the culture they maintain, and since the culture of the Western World is largely dependent upon the elements contributed by Greece and Rome, it may well be that the educational future of the classics will no longer be so exclusively linguistic in form as heretofore. Many American colleges and universities are now giving courses in which the outstanding achievements of the classical world are presented to the student body in English, without the benefit of the original language. In the high schools, too, cultural material plays a large part in many of the new courses in General Language (*q.v.*), in which Latin and Greek and their *realia* play a part.

The able and interested student will continue to be drawn to the study of the classical languages and literatures for the reasons which have caused their survival to the present day. The contributions of the Greeks and Romans; however, must be made avail-

able also to those whose primary interests are not linguistic, æsthetic, or philosophic, but who are to be educated to an intelligent inheritance of the past. K.G. and R.H.T.

CLASSIFICATION OF STUDENTS.

In practically all elementary schools and in some high schools children are taught as if they were at the same level of ability in all subjects. They are classified into "grades" and move from one grade level to the next at specified times if their work is evaluated as of promotional quality; otherwise they remain in the same grade until the next promotion date. Since there are exceedingly few cases, if any, where a child is at the same grade level of ability in all his subjects, class instruction at one grade level does not meet individual needs. The departmentalized system, where children may be at different levels in different subjects is not advocated for the elementary school since it means that the pupil has several teachers each day, with no teacher knowing him sufficiently well to give him the all-round guidance so necessary at this age level.

A few schools, emphasizing the education of the "whole" child and recognizing individual differences of ability and interest at every age level, keep children together in a class of their own age group, labeled the "Sevens" or the "Elevens" rather than Grade II or Grade VI, and make special provision by their teaching methods for adapting instruction to individual needs. In these schools there is no "promotion" in the usual sense of having achieved "passing marks" in subject-matter. Sometimes it is considered advisable to transfer a child from one group to another, but this is done not on any criterion of failure or of ability for rapid advancement but on the judgment that the particular child's development—mental, social and emotional—will proceed better in the group to which he is transferred.

In many city public schools where there are sufficient children of one grade level to

form more than one class, the popular method for adjusting to individual differences within a grade level has been *ability grouping* or *homogeneous grouping*, as it is often called. This procedure recognizes the fact that all children who are promoted to a particular grade are not of equal ability and it therefore divides them into several groups according to a combined criterion of I.Q. and general school achievement. This method of grouping children does not take into consideration the fact that a child is not at the same level of ability in all subjects and skills. The adjective "homogeneous" is thus a misnomer, although since achievement in every school subject has a positive, if often very low, correlation with I.Q., the range of variability is reduced.

Ability grouping has been condemned on the grounds that it is inadequate to care for differing mental abilities, that the method of segregating children often leads to personality maladjustments, and that the procedure is undemocratic and develops undemocratic character traits. It is easily demonstrated that ability grouping, used without any other reorganization of the grade system, is inadequate to care for variation in ability. Variation in I.Q. means variation in speed of learning. Schools having ability grouping nevertheless often expect all groups of the same grade level to complete the work of that grade during the same period of time. The "brighter" classes are given extra work to do on the same grade level to keep them going through the grades at the same pace as the slower groups. Thus the children least in need of repeating the same concepts in different contexts are the ones who get extra drill. Sometimes the "enrichment" program for the brighter classes consists of taking them on more trips and letting them have more first-hand experiences, while the duller children are given more verbal drill. While slow children can learn facts verbally by rote drill, they are the ones who need more direct first-hand experiences in proportion to the amount of verbal teaching given them, if they are to learn with understanding. These fallacies, added to the working assumption of the majority of teachers that once there has been ability grouping the pupils are alike in all abilities so that there is little need for further adaptation to individual differences,

condemn ability grouping in the eyes of many educators.

The argument against ability grouping from the mental hygiene point of view is based on the expectancy that the procedure will bring about an increase in inferiority feeling. While this is certainly true for some children, especially for those whose level of aspiration has been raised beyond their ability owing to the goals set them by parents, the effect is offset by other pupils who become better adjusted because face-to-face competition with superior children has been lessened. Schools that have adopted ability grouping have had no significant increase or decrease in maladjustments.

The argument that ability grouping is undemocratic is regarded as invalid by most educators if it means that all children must be considered as being equal in ability and that they must be taught alike. Democratic ethics, far from demanding that we disregard individual differences, demand that we so take care of individual differences that each person can grow to his maximum possible well-being. From the democratic point of view, the serious argument against ability grouping is that it may produce character traits not suitable in democratic citizens. If the brightest children, because of little contact with the duller ones, were to develop the attitude that the wishes and opinions of the masses need not be respected and that it is up to the aristocracy of the intelligent to decide what is good for all, then indeed ability grouping would be a dangerous educational procedure in a democratic society. Equally disastrous would be the acceptance on the part of the average and slow pupils of a submissive waiting-to-be-told-what-to-do rôle. Though it has not been proved that such attitudes need necessarily develop, their dangerous possibility has to be taken into account in the administration and teaching of ability groups.

There are other forms of ability grouping besides the procedure of "homogeneous" grouping within a single grade. In one or more grades of the school system, especially in junior high schools, the brightest of the groups instead of having an "enrichment" program is turned into a "rapid advance" class and helped to do the work of a whole year in half the time. Classes for the mentally retarded (defined as children having

I.Q.'s of 75 and lower), where yearly promotion from grade to grade is not expected, are a special instance of ability grouping, matched now in a few places with special classes for the very bright (usually defined as I.Q.'s of 130 and over), where the children need not slow down to do the work of only one grade in one year. These special classes differ from the ability groupings within a grade in that though they include only one area of intelligence, they consist of children of various ages and of various school grades because of the fact that at any age level fewer than 5 per cent of the children will be found to have I.Q.'s below 75 or above 129.

In high schools and colleges students are classified mainly in terms of the curriculum which they are pursuing. Ability grouping, or sectioning, is often carried out in courses where there are sufficient students to be so divided. In required high school subjects, a "three-track plan" corresponding to the XYZ ability grouping of the elementary schools is sometimes instituted. Since most high schools are departmentalized, it is possible to section students differently in different subjects. Special subject-matter prognosis tests can be used for placement instead of an intelligence test or a test of general achievement. The differentiation of high school curricula in itself is meant not only to result in a classification of students according to their interests but also according to their abilities. By and large, the brightest students are urged to pursue an academic curriculum (including mathematics, science, and foreign language) qualifying for college entrance, while the slower are advised to pursue a "general" or a vocational curriculum.

Classification of students according to sex, once so popular, is practically absent in elementary public schools of today. It sometimes occurs at the high school level and is more prevalent at the college level. Such classification is effected by providing separate schools for boys and girls rather than by segregating the sexes into different classes within one school. (See CO-EDUCATION.)

CLASSROOM (CONSTRUCTION AND DESIGN)—See BUILDINGS, SCHOOL.

CLEFT PALATE SPEECH — See SPEECH CORRECTION.

CLERICAL STAFF, SCHOOL. Authorities on school administration believe that school units with fifteen or more teachers should have at least a half-time paid assistant. If there are more than twenty-five teachers, there should be a full-time paid secretary. Such a person is considered to be a good investment even in smaller systems. One of the most appalling wastes in American education is the extensive use of high-salaried school administrators to do clerical work which can be performed efficiently by clerks at much less cost.

The use of pupil part-time help in the smaller school units is practiced extensively but is not universally regarded with favor. There are many functions of a school clerk which cannot or should not be performed by pupil workers. It is considered better practice to use a paid employee, for example a commerce teacher or librarian, to give part-time to important clerical work of the school. Certain routine tasks might well be performed by competent pupils as a part of their educational experience. The larger school systems employ additional clerks and make the services more specialized. When practicable, it is recommended that school clerks be placed under civil service regulations. Where civil service cannot be used to assure competence, a few qualifications such as the following should be adhered to for the superintendent's secretary or the main clerk in the school office: she should be a college graduate, preferably with some education courses; she should dress neatly; she should speak correct English; she should write and spell well; she should be courteous to visitors; and she should have a pleasant voice. Minor clerks might be of more limited and specialized ability.

The duties of the school clerk or clerical staff include: (1) general stenography; (2)

filing, indexing, etc.; (3) meeting people and answering questions, whenever possible sparing the administrator; (4) compilation of reports; (5) keeping records; (6) handling money; (7) taking telephone calls and making appointments; (8) keeping calendar of events and of reports or notices due; (9) taking care of office machines; (10) posting notices, mailing, etc.

Clerical service to teachers to relieve them of clerical duties which interfere with their teaching efficiency is advocated when the school unit is large enough to support more than one clerk. Where careful study has been given to waste of administrator and teacher time in routine clerical duties, school boards have found it good economy to increase rather than diminish clerical service. The greatest waste is in the smaller schools where too often no clerical assistance is provided.

CLINIC, SCHOOL. School clinics are usually provided by local boards of education for maintaining and, if possible, improving the health, both physical and mental, of school children.

The clinics organized by schools are of four kinds: (1) health; (2) dental; (3) educational; (4) child guidance. Sometimes two or more of these are combined for purposes of administration. The functions and personnel of these clinics vary with the type of service rendered.

The functions of the health clinic are (1) to provide special and periodic examinations of eyes, ears, and general health; (2) to prevent the spreading of communicable diseases; (3) to treat minor ailments and accidents; (4) to give health instruction.

Usually a full-time physician or a school nurse is in charge. When a nurse is in charge, the services of a part-time physician are always provided. In larger cities a staff of specialists is usually available. The clinics

CLOCK HOUR — CLUBS, SCHOOL

seek to improve children's health chiefly by detecting and preventing disease. Reports are made to parents who are urged to take the children to their family physicians or to specialists for treatment. In some states, however, schools provide supplementary feeding for undernourished children and arrange for glasses and other services when parents cannot afford them. One of the chief duties of the nurse is to follow-up the cases to assist where necessary in seeing that the children's needs are properly cared for. Accurate health records for each child are kept.

The dental clinics are usually in charge of a full-time dentist or dental hygienist. The services rendered at these clinics are (1) making periodic examination of the teeth; (2) cleaning teeth; (3) doing minor repairs; for example, filling small cavities; (4) instructing children in the care of teeth. In smaller school districts, dental clinics are often only part-time clinics.

Educational clinics are sometimes referred to as speech or reading clinics. While speech and reading correction constitutes a large part of the work of these clinics, deficiencies in other subject-matter fields are also treated. The functions of educational clinics are (1) to study the child's problem and diagnose the difficulty; and (2) to carry out remedial procedures. Specialists in diagnostic and remedial work are in charge of these clinics. Frequently psychologists are attached to these staffs to give intelligence and achievement tests and to render other psychological services. (See also REMEDIAL READING; SPEECH CORRECTION.)

Child guidance clinics (*q.v.*) are maintained by the schools of some of the larger cities to study and treat the behavior problems of children. The staff of these clinics is usually composed of a psychiatrist, in charge; a psychologist; and a psychiatric social worker.

Some few schools provide special clinics for orthopedic cases but these cases are most frequently served by the health clinic. (See HEALTH.)

CLUBS, SCHOOL. School clubs may be defined as organized groups of students whose interest and program center about some particular subject or activity, often beyond the scope of the regular curriculum. Usually a meeting is held once a week either on school time during the activity or club period, or after school. That this is a popular school activity is evidenced by the fact that the writer has found a total of 390 different clubs in American schools. The secondary schools have made more extensive use of school clubs than have the elementary schools, but the latter are organizing clubs to an increasing extent.

In addition to the development of friendships among students and the fostering of group loyalties, the main objectives of school clubs are to widen and to deepen student interests. A good schedule offers a considerable number and a wide variety of types of clubs—academic, recreational, service, personal culture, and independent cooperating organizations—which are open to all students with few or no limitations. Hence the student can widen his range of interests by selecting from this list. Some schools allow a student to belong to more than one club at a time; others allow him to belong to a club for a limited time only, say a year or two; these devices increase his "interest widening" possibilities. Interclub program exchanges and visits, and assembly programs and public exhibits reflecting club work also help in the widening process. In the second place, the club offers an excellent opportunity for the deepening of the student's interest by allowing him to specialize in the things that appeal to him.

Naturally, this widening and deepening of student interests can play a most important part in the discovery, development, and proper capitalization of the student's cultural, vocational, social, and recreational interests and abilities.

While perhaps not an objective of school clubs, certainly an important value is their influence in enriching, supplementing, and motivating curricular work. Club work is usually informal, nonuniform, is student-centered and student-dominated, and is voluntary. The fact that club work and class-work supplement each other is proved by the fact that academic clubs are beginning to disappear by being assimilated into the corresponding subjects.

The usual club setup provides for free and unlimited choice of clubs by the students, with restrictions only as to sex and size of group. Such restrictions as teacher-selection of members, student balloting, and fees, dues, and assessments are to be deplored. The only requirement for membership should be an appropriate interest in what the club has to offer.

Close supervision and continuous evaluation help to insure that club time is well spent. The formal chartering of a club by the student council, especially in the case of a new organization, also represents a valuable administrative technique. In its formal application for a charter, the group sets forth its purposes, name, membership requirements, organization, and activities. The council, after examining these carefully and finding them satisfactory, formally charters the club or suggests changes before making a final decision. Such charters may be revoked for good reasons. Formal initiations, secret signs, handclaps, passwords, insignia, and the like characterize the secret society and have no place in the club program.

Club activities center about the main interest of the group, and may take the form of formal and informal programs, individual and group projects, social and recreational events, interclub programs and visits, exhibits and assembly programs. Often a "club night" is staged for the general public. (See **EXTRACURRICULAR ACTIVITIES.**) H.C.M.

CODE OF ETHICS—See **ETHICS, PROFESSIONAL.**

CO-EDUCATION. Co-education means the provision of instruction for both sexes in the same institution and with the same instructors. The practice today is almost universal in public elementary and secondary education in the United States and is general in higher education, but it has not always been so.

Before the nineteenth century secondary and higher education for women was relatively rare, education beyond elementary needs being the prerogative of men. When girls were given advanced instruction it was in special schools of two main types. One trained servants for household duties; the other was known as the "finishing school" and provided a superficial polish. There was little recognition of the truth that the education of women involves the same problems, responsibilities, and rights as the education of men.

With the opening of the West in America, the common education of boys and girls went forward rapidly and as an accepted principle. It was a logical adjustment to frontier conditions. The people were committed to free public education. Separate schools when pupils were few were economically impossible or inadvisable. When secondary schools appeared they, too, for the same reason, admitted boys and girls on an equal footing. The schools organized on this footing continued to grow and to win public support. In no part of the country except in the East is any distinction now made in elementary and secondary education of boys and girls. Only in a few large cities of the Atlantic seaboard and in some of the larger southern cities are there separate boys' and girls' high schools in the public school system. Catholic secondary schools, however, are generally not co-educational.

Later the movement spread to the colleges. Most of the western state universities which opened after 1850 were co-educational from the first. All of the state universities now thought of as Western are open to women.

The southern states made the concession more slowly. Today national public opinion has definitely affirmed the rights of women to share equally with men the instructional facilities of schools, colleges, and universities.

The trend today is in the direction of extending co-education; some authorities even predict that another fifty years will see co-education become the universal system of public instruction on all levels. There are two important exceptions to this trend. The Catholic Church is outspoken in its objection to co-education and tolerates it in some parochial schools only because of economic considerations. There are, too, nations that object to co-education. In most Latin-American countries, for example, there are separate educational facilities for boys and girls except in primary schools and in institutions of higher learning. COLLATERAL READING. Collateral reading refers to additional materials that are coordinate in rank and function with the basic reading requirement. If a basic textbook is used in a subject, then the collateral reading is found in other books dealing with the same subject or topic. The purpose of collateral reading is to secure further information than can be found in one or two sources. Since no two writers give the same emphasis to a topic or present the same viewpoints, the reading of several books gives a broader and more detailed treatment than can be found in one book.

The expression collateral reading implies that this use of additional materials is supplementary to that of the basic textbooks. In modern methods of teaching, however, the tendency is to reduce the pupils' reliance on a single textbook and to use the textbook more as a convenient source of information

to be consulted when necessary and as a means of building a common background for class discussion. The textbook itself is therefore used in the way in which collateral reading was formerly used. Moreover, this changed attitude towards the textbook reduces the need for reliance on a single basic textbook and increases the desirability of using many books as sources of information and as expositions of points of view. The expression collateral reading thus becomes less important because these books are now accepted as part of the basic background and not as a means of supplementing or correcting the point of view of a single official textbook.

The use of collateral reading has been extended further by the increasing popularity of the activity program in elementary schools, with its encouragement of research activities and committee reports even in the lower grades. Thus all pupils, from the youngest pupils in the primary grades to the young men and women in our colleges, are becoming accustomed to using a wider variety of reading materials than was the practice a few years ago. COLLECTING—See ACQUISITIVENESS.

COLLEGE—See COLLEGE EDUCATION FOR WOMEN; JUNIOR COLLEGE; LIBERAL ARTS COLLEGE; MUNICIPAL COLLEGES AND UNIVERSITIES; STATE COLLEGES AND UNIVERSITIES.

COLLEGE ADMINISTRATION. The *administration* of colleges, with the exception of some denominational colleges, is usually conducted by boards of control. The membership of such boards ranges from five to two hundred and fifty. Administrative control is either public-state controlled; or private non-state controlled. Even the latter may be thought of as partially state controlled, since these institutions are usually chartered under state law, and since many of them receive part of their support from public funds.

Internal administration is under the control of a president, responsible directly to the board of control, and the faculty. The faculty is usually the legislative body in educational matters; the president and board exercise wide powers over larger educational policies. In recent years the faculty has had an increasing voice in the determination of the insti-

tution's policies. There is almost always a dean who is the administrative head of the college. In a university there is a dean, sometimes called "director", for each college or school. There are also deans of men and of women; sometimes, deans of administration. Service units, such as physical plant, library, student records, and financial accounting, are set up as separate administrative units, each with its administrative head who is usually responsible directly to the president. Within each school or college there are academic departments, each of which has a head or chairman, who is usually appointed by the president, although he may be chosen by the faculty members of the departments.

In a university there is usually, in addition to the separate faculty of each college or school, the all-university faculty, frequently called the senate, composed of members from the several faculties according to academic rank or election. In large institutions there is frequently the president's cabinet or administrative council, whose membership is composed of the deans and in some cases other administrative officers. (See also COLLEGE FACULTY; LIBERAL ARTS COLLEGE). R.A.K.

COLLEGE ENTRANCE EXAMINATION BOARD. President Eliot of Harvard was considered visionary when, in 1877, he made the first suggestion containing the idea of a college entrance examination board. In February, 1896, in an address delivered before the Schoolmasters' Association of New York and Vicinity, he gave an outline of his proposal. In December, 1899, Nicholas Mur-

ray Butler of Columbia presented a detailed plan for such a board, which corresponded closely to what was finally adopted and followed for more than a third of a century.

A plan for a college entrance examination board was submitted in November, 1900, by a committee of which Dr. Butler was chairman, and was adopted at a meeting which comprised representatives of eleven eastern colleges and nine representatives chosen by the Association of Colleges and Preparatory Schools of the Middle States and Maryland. President Seth Low of Columbia University was elected chairman, President Thomas of Bryn Mawr vice-chairman, and Nicholas Murray Butler secretary of the new organization.

Nine hundred and seventy-three candidates presented themselves at the first examinations, which were held in June, 1901, at sixty-seven points in the United States and at two points in Europe. In 1941, 23,620 candidates registered for the examination. Prior to 1940 there were between seventy-five and one hundred candidates examined annually at Brussels, Florence, Venice, Geneva, London, and Paris. In 1940 there were twelve examination centers outside the United States, three being in South America.

The College Entrance Examination Board is an agency set up for the purpose of securing uniformity in the administration of examinations to high school graduates for entrance to institutions of higher education. Its functions include, first, drawing up syllabi for the subjects covered in the examinations, and aims to be sought in the teaching of certain secondary school subjects; and, secondly, providing means by which examination questions are constructed and papers are marked on impartial bases.

The Board now consists of six members chosen at large from secondary schools, eleven members appointed by the various regional associations on and contiguous to the Atlantic Seaboard, and forty-five members representing universities, colleges, and scientific schools. (Of the 1941 membership, only four college and three secondary school members represented the territory west of Pennsylvania.) Besides an executive committee of nine, the Board has seven other standing committees.

In 1926 the Board introduced a new type of test, called the Scholastic Aptitude Test,

COLLEGE ENTRANCE REQUIREMENTS

which consisted of two parts—one measuring familiarity with the words in the English language, and the other mathematical aptitude.

Previous to 1940 there were two examinations a year—the Scholastic Aptitude Test in April, and regular subject-matter examinations in June. Beginning in September, 1940, another subject-matter examination was added, covering college preparatory courses. The Board also has been giving, in eleven subjects or fields, a third type of examination, called Achievement Tests. They are of the objective or restrictive response type. Nine of these tests are offered, of which any one candidate may take only three.

The above procedure was followed until 1942, when the June subject-matter examinations were withdrawn, with the exception of the Mathematics Attainment Test, Part One. The June examinations now consist of the Scholastic Aptitude Test, Achievement Tests, and the Mathematics Attainment Test, Part One.

COLLEGE ENTRANCE REQUIREMENTS. The term college entrance requirements, as here considered, refers to the standards which degree-granting institutions stipulate shall be met by applicants for unconditional admission to freshman status and candidacy for a degree. These standards vary among institutions and from year to year in the same institution with, however, certain definite patterns and trends evident.

At the present time, the one entrance requirement common to practically all the colleges of the United States is secondary-school graduation, usually with a minimum of 15 or 16 acceptable units. Even this standard has been temporarily suspended by a number of institutions in an effort to meet the demands of a war-time economy. Other current requirements are set forth in *Table I*, the data of which are based on a study (M. Hunsinger, "The Selection of Persons to Be Trained as Teachers of Commercial Subjects," unpublished doctor's thesis, University of Pittsburgh, 1942), of 371 representative colleges of the United States. The institutions studied represent 46 states; include 81 state universities and colleges, 83 state teachers colleges, and 207 non-state universities and colleges; and range from very large universities to very small private colleges. The information used was taken from official catalogues for the

TABLE I
ENTRANCE REQUIREMENTS SPECIFIED BY 371 REPRESENTATIVE COLLEGES
IN THE UNITED STATES

Entrance Requirement	State Universities and Colleges (81)		State Teachers Colleges (83)		Non-state Universities and Colleges (207)		All Combined (371)	
	No.	Per cent	No.	Per cent	No.	Per cent	No.	Per cent
Specific secondary-school units ...	64	79.0	46	55.4	173	83.6	283	76.3

Acceptable personal interview	0	0.0	7	8.4	7	3.4	14	3.8

school year, 1940-41, and was verified by staff members of the colleges represented. Approximately three-fourths of the institutions represented demand that the secondary-school transcript show credit in certain specific subjects. Other requirements, none of which is common to a majority of the institutions studied, may be ranked in order of frequency as: (1) Evidence of approved moral character; (2) satisfactory scholastic average or rank in secondary-school graduating class; (3) good health, as evidenced by physical examination or physician's certificate; (4) recommendation by principal or other secondary-school official; (5) evidence of approved personality; (6) satisfactory score on a psychological examination or college aptitude test; (7) letters of recommendation other than those given by secondary-school officials; (8) minimum age requirement of fifteen or sixteen years; (9) evidence of scholastic or professional interest and promise; (10) satis-

factory scores on achievement examinations; and (11) an acceptable personal interview.

Curriculum patterns. Among the specific secondary-school units which colleges state shall be presented for admission, English is the most common; but mathematics, social science, science, and foreign language occur frequently. The prescribed pattern may allow practically no electives; it may allow electives for all except three or four units; or it may designate that two-unit or three-unit sequences be chosen from the various academic fields and that the number of free electives be limited. The data of *Table II* depict the distribution of secondary-school units according to subject-matter fields and summarize the miscellaneous restrictions imposed on acceptable units as prescribed by 200 of the institutions surveyed in the above-mentioned study. Approximately one fifth of these colleges make no specification concerning curriculum patterns presented.

TABLE II

GENERAL DISTRIBUTION OF SECONDARY-SCHOOL UNITS SPECIFIED FOR ADMISSION
TO 200 REPRESENTATIVE COLLEGES

Subject-Matter Field in Which Units Are Specified	State Universities and Colleges (45)		State Teachers Colleges (50)		Non-state Universities and Colleges (105)		All Combined (200)	
	No.	Per cent	No.	Per cent	No.	Per cent	No.	Per cent
English	40	88.9	30	60.0	88	83.8	158	79.0
Mathematics	28	62.2	21	42.0	63	60.0	112	56.0
Social science	30	66.7	22	44.0	55	52.4	107	53.5
Science	14	31.1	16	32.0	42	40.0	72	36.0
Foreign language	7	15.6	2	4.0	30	28.6	39	19.5
Miscellaneous Specifications								
Definite pattern of major and minor sequences	8	17.8	6	12.0	6	5.7	20	10.0
Maximum number of units in non-academic courses acceptable ..	21	46.7	6	12.0	32	30.5	59	29.5
Additional restrictions on acceptable units	6	13.3	5	10.0	23	21.9	34	17.0
No definite curriculum pattern designated	5	11.1	20	40.0	16	15.2	41	20.5

The number of units specified in the subject-matter fields also varies. Among the 200 colleges reporting entrance requirements, the following specifications are made:

English: three units by 66 per cent; four units by 12 per cent

Mathematics: two units by 32 per cent; one unit by 17 per cent

Social science: one unit by 33 per cent; two

units by 15 per cent

Science: one unit by 32.5 per cent; two units by 2.5 per cent

Foreign language: two units by 14.5 per cent; one, three, four, and five units each by 1.0 per cent

Two typical patterns of major and minor sequences designated by some colleges instead of minimum numbers of units in def-

COLLEGE ENTRANCE REQUIREMENTS

inite subject-matter fields for distribution of secondary-school courses are: (1) Three units in English and other units so selected as to present one major sequence of 3 units and two minor sequences of 2 units each from foreign language, mathematics, laboratory science, and social studies. (2) Three units in English, one unit in mathematics, one unit in social science, and other units so selected as to present two major sequences of 3 units each and two minor sequences of 2 units each from academic subjects.

The most common restriction on curriculum patterns accepted for admission to college in addition to those listed above is that a limited number of "non-academic" or "vocational" courses be presented. The so-called non-academic courses commonly include agriculture and home economics; manual arts; speech, dramatics, and journalism; music and art; and business subjects. Frequently, not more than three, four, or five of such units are accepted.

Trends. Evidence that entrance requirements are not static but in an almost continuous process of revision in the colleges of the United States is manifested by the constant changes in statements of admission policies found in college catalogues. That the general trend at present is toward more liberalism in curricular specifications and more consideration of each applicant's personal qualifications is revealed by the data in *Table III*

TABLE III
CHANGES IN ENTRANCE REQUIREMENTS IN
50 REPRESENTATIVE COLLEGES BETWEEN
1931 AND 1939

Change	No. of Colleges	Per cent Specifying
Less specification in curriculum patterns	25	50
Greater specification in curriculum patterns	1	2
No change in curriculum patterns specified	24	48
Increased emphasis on qualifications other than specified curriculum patterns	21	42

showing types of changes in entrance requirements made by 50 representative colleges between 1931 and 1939. (Comparative data were obtained from admission requirements reported in the Second Edition [1932] and the Fourth Edition [1940] of *American Uni-*

versities and Colleges, a Handbook of Higher Education prepared by the American Council on Education. The 50 colleges included were selected somewhat at random, but approximately ten pages apart, from the earlier edition of the directory.)

Although the number of colleges which prescribe no specific curricular requirements is increasing, many institutions continue to define entrance standards in terms of minimum numbers of secondary-school units. These schools, however, are prescribing fewer units and less definitely than formerly. The most common changes in curriculum specifications for admission in the 50 colleges surveyed were found to be: (1) reduction in the number of units of mathematics required by 24 per cent of the institutions; (2) reduction in the number of units of foreign language required by 20 per cent of the institutions; (3) change from a specific history requirement to social science requirement by 16 per cent of the institutions; and (4) change from definite course designations to specification of major and minor sequences by 8 per cent of the institutions.

At present some colleges, desiring to place emphasis on the high schools from which graduates are accepted or on the personal qualifications of the applicants rather than upon uniformity of preparation, make the statement of their requirements indefinite in order to permit admission of promising students regardless of their secondary-school programs. Illustrative of this tendency is the statement occurring ever more frequently in college catalogues that acceptance is based upon evidence of ability and character rather than on any rigid pattern of units and that the student's record will be evaluated if he presents a transcript from an accredited high school, is well recommended, and shows satisfactory intellectual aptitude. Thus liberalization of curriculum patterns has brought attempts by colleges to emphasize attainment rather than credits and to substitute other admission standards for minimum numbers of units. As shown in *Table IV*, greater consideration is at present being given to the applicant's scholastic standing or rank in graduating class; the recommendation of his secondary school principal; his evidence of approved moral character, health, and personality; and the acceptability of his rating on

COLLEGE FACULTY

a personal interview or a psychological examination.

TABLE IV
ENTRANCE REQUIREMENTS ADDED BY 50
REPRESENTATIVE COLLEGES BETWEEN
1931 AND 1939

Requirement	No. of Colleges	Per cent Specifying
Acceptable scholastic standing or rank	9	18
Recommendation by secondary-school official	8	16
Approved moral character ...	5	10
Good health	3	6
Acceptable personal interview	3	6
Satisfactory score on psychological examination	2	4
Approved personality	2	4

The trend in college entrance requirements over a longer period of time is illustrated in modifications in policy of a fairly conservative eastern college. In 1910, the specifications for admission were: English, 3 units; electives, 3 units. In 1916, they changed to: English, 3 units; mathematics, 2 units; foreign language, 4 units; science, 1 unit; and electives, 5 units. In 1938, the foreign language requirement was reduced to 2 units, and it was stipulated that the electives should include 1 unit of social science and not more than 4 units from non-academic subjects. Now, in 1943, the admission requirements are: graduation from an approved secondary school, with 4 units of English and 12 additional units, of which not more than 5 are non-academic in character; and approval by the Committee on Admissions of the applicant's preparation and ability for his selected college work and of his personal qualities, such as social responsibility, cooperativeness, and loyalty.

Impetus for the gradual liberalization of college entrance requirements seems to have come largely from the high schools, whose officials believed that needless unit specifications for admission to college were preventing the broadening of curricula and enrichment of courses desirable in adapting the secondary-school work to the individual student and to the community. Even when high schools established curricula that did not prepare for college, a large percentage of the pupils not expecting to attend college chose the college-preparatory programs. So, not willing to be

dropped from the accredited list, many high schools continued emphasis on foreign language and mathematics while their principals criticized college policy and brought such pressure as they could to effect changes.

General factors influencing the trend of changes in college entrance requirements are: increased cooperation and articulation of programs between high schools and colleges in recent years; wider ranges in the intellectual abilities of students attending high schools and colleges; a tendency toward student-centered teaching and an increased emphasis on developing citizens rather than scholars in both high school and college; increased reliance of school officials on aptitude tests, personal interviews, and cumulative records; the growth of junior colleges; the failure of the old plans of admission to assure college students of high ability and thorough preparation; the high percentages of students who attain honors when admitted under special plans; and the accumulating evidence of research against the theory that specific courses pursued in high school affect the student's probability of success in college. (See also EIGHT YEAR STUDY; LIBERAL ARTS COLLEGE.)

M.H.

COLLEGE FACULTY. The members of the teaching staff of a college or university are usually referred to as its *faculty*; some institutions, however, restrict the term to refer only to those members of the staff who hold professorial rank, and use the expression *instructional* staff to include all of the teachers, whether they be of professorial or lesser rank.

Though the actions of the faculty are subject to review by the college administration and the board of trustees, the college faculty has the opportunity of exerting much more influence in shaping the educational policies of the institution than do teachers in the elementary or secondary schools. As a rule the faculty votes to confer degrees on students and passes judgment on proposed changes in the curriculum. The faculty is thus often responsible for determining standards of scholarship, for planning the distribution of credits among the various courses in the curriculum, for defining the nature of the college course, and for deciding many of the other educational problems of college work. The faculty

COLLEGE FACULTY

is often a reviewing body of departmental action. When it is too large for effective functioning as a legislative body, many of its functions may be delegated to a *Faculty Council* or executive committee, consisting either of the senior members of the faculty or of the elected representatives of the faculty. The authority and the prestige of the college faculty vary considerably among the different colleges, usually being greater at the larger universities than at small denominational colleges. At some institutions the members of the faculty elect the chairman or executive officer of their respective departments and have a voice in selecting candidates for appointment and for promotion to higher rank; at other institutions the college faculty has no jurisdiction in such matters.

Unlike the members of instructional staffs of school systems who are divided into only two ranks—teachers and supervisors—the members of the college faculty are of many different ranks. Ordinarily the lowest rank of a regular college teacher who carries a full-time teaching program is *instructor*. Such ranks as *fellow*, *tutor*, and *assistant* are interpreted variously at different colleges but usually apply to young teachers, often graduate students, who do not carry a full teaching program and generally enjoy few if any of the legislative privileges accorded other members of the instructional staff. Above the rank of instructor are the *assistant professors*, *associate professors*, and *professors*. Denominational colleges tend to have many more full professors than either assistant professors or instructors, but in state and municipal institutions the proportion of full professors is very little larger than that of assistant professors or instructors. Of all full-time college teachers, more than one-third hold the rank of instructor and about half are either associate professors or full professors.

At least half of all faculty members have a Ph.D. degree or its equivalent; the percentage may be as high as 85 per cent for a single college. A relatively small percentage of college teachers have only a bachelor's degree. Accrediting associations in general have been an influence in increasing the proportion of faculty members who hold advanced degrees. Though the increase in the number of college teachers who hold the doctorate undoubtedly has improved the scholarship of

college faculties, objection has been raised in many quarters to the influence which the possession of the Ph.D. has on appointment and promotion. Some critics have pointed to the low correlation between the amount and character of graduate work taken by college teachers and their effectiveness as teachers. Others have criticized the universities for ignoring the fact that many of their graduate students are preparing for college teaching; these critics see no reason why universities should not prepare their graduate students to deal with the educational problems which confront college teachers. There is little evidence, however, that these objections have reduced the prestige of the Ph.D. as an accepted part of the college professor's background.

Since most colleges are autonomous, there is considerable variation among colleges with respect to such matters as salary, conditions of appointment, requirements for promotion, tenure, and provisions for leaves of absence and retirement. College teachers are, on the average, better paid than are elementary and secondary-school teachers, although both the average and the maximum income of college professors are lower than the average and the maximum income of members of such other professions as law, medicine, and engineering. The salaries of college teachers normally reflect changes in the economic status of the times, although college teachers' salaries usually lag behind those of the general population, both in rising during periods of prosperity and in falling during periods of depression. Of the requirements for appointment and promotion, the two criteria used most frequently are scholarship, as reflected in the record of graduate study and publications, and teaching ability. Permanent tenure is not so commonly accepted a feature of college teaching as of elementary and secondary school teaching. Many institutions employ all teachers on an annual contract, and even full professors sometimes have contracts for only two or three years at a time. The American Association of University Professors has been quick to investigate and to publicize instances where the dismissal of college teachers involved violation of the principles of academic freedom and has been consistent in its efforts at improving the conditions of tenure of college teaching. An increasing number of colleges have made provision for

granting sabbatical leaves of absence and for establishing a pension or retirement fund. (See LIBERAL ARTS COLLEGE.) R.A.K.

COLLEGES, LAND GRANT — See LAND GRANT COLLEGES.

COLOMBIA, EDUCATION IN. By 1930, Colombia had a population of some 8,500,000—white, *mestizo*, Indian, and Negro—scattered over 450,000 square miles of territory which is covered with lofty mountains and tropical valleys and plains. Of its three classes of people, the upper were cultured; the middle, weak and slightly educated; and the lower, ignorant and helpless. For the few rich, education followed nineteenth century French patterns; for the immense majority of the poor, it tried to keep alive the old, Colonial patterns, which stressed moral and spiritual values almost to the exclusion of others. Thus, in a country known for its simple pastoral and agricultural economy, ten per cent of its people reached the levels of advanced education in colleges and universities that offered courses in art and literature, in logic and metaphysics, in higher mathematics and jurisprudence, but not in applied sciences and experimental research; while the rest were expected to attend public schools that taught urbanity, meekness, poetics, and sacred history, but not sanitation, home economics, agriculture, and the like. Out of 1,500,000 children of school age, only some 400,000 "went to school" in dark, unsanitary old houses, where education was nothing but drudgery and a menace. A radical reform was necessary, and it came mainly because of the efforts of a great educator, Dr. Agustin Nieto Caballero, and a genuine and inspired

sociologist, Dr. Luis Lopez de Mesa, who, together with Señor Gustavo Santos and Dr. Carlos Gracia-Prada, reorganized the Ministry of Education of Colombia, and proceeded to reorganize its whole educational system in accordance with certain ideals and principles which were to be put in operation later on by such men as Jorge Zalamea and German Arciniegas.

The first concern of the reformers and their followers was to study, carefully and honestly, all vital conditions in the various regions of Colombia, high and low, cold and warm, and then to establish the ways and means to protect and strengthen the physical, intellectual, and social welfare of Colombian children of both sexes, regardless of their race, origin, and economic position, and without neglecting their moral and spiritual advancement. *Education for all* was the battle cry of the reformers, education for the better life, education to lead boys and girls into becoming healthy, joyous, and useful citizens of Colombia and of the world.

The system created by the reform calls for the establishment of the following educational cycles and institutions:

(1) Elementary, two years—Kindergartens;

(2) Primary, five years—public schools;

(3) Complementary, two years—Vocational schools in the cities and agricultural schools in the rural districts;

(4) Secondary, six years—Schools of humanities (*colegios de bachillerato*), for those who intend to attend the universities, and industrial and commercial schools for the others; and

(5) Professional, from four to six years—Universities and Normal Schools.

The reform followed in general the leadership of such world-known educators as Horace Mann, Dewey, Montessori, (*qq.v.*) and others; but it aimed, to make their ideas and methods fit into the needs of the Colombian people and the land in which they live. Thus, to promote the social welfare of the children, there have been established clubs, committees, etc.; to develop their æsthetic sense, there have been organized orchestras, museums, art galleries, etc.; to promote their physical welfare, there have been built gymnasias, playgrounds, and athletic plants; but there have also been created such institutions

as the *colonias escolares*, some located on the high lands and others on the low lands. These locations allow for the transfer of children from the latter to the former, and vice versa, thus giving the children the chance to experience a year's change of climate, so necessary in tropical countries.

Being well aware of the temperament and the traditions of the Colombian people, those in charge of this educational reform decided (a) to establish co-education only in the elementary and advanced stages, that is, in the kindergartens, public schools, and universities, but not in the secondary schools; and (b) to start educational processes from the concrete and the local, and continue them toward the abstract and the universal: the *centros de interes* (projects) take children from their school and home environment to the understanding of world affairs, during their first ten years of schooling, but take them back to a thorough knowledge of Colombia in all its many aspects—economic, social, political, and cultural—during the last two years of their secondary education.

All the *programas de estudio* (curricula) were changed for the public and secondary schools of the country, and in order to meet their demands, many and new institutions were created for the preparation of teachers, such as the *cursos de informacion* (intensive courses), the *escuelas normales de rurales* (normal schools for rural teachers), the *normales nacionales* (normal schools), and the *Facultad de Educación* (national college of education). By 1935 there were in Colombia some eleven private and public "universities," of which the National was the most important. In 1935 the series of independent professional schools in Bogota, which comprised the National University, was reorganized by national law into a centralized university with a unity of purpose and a new spirit of cooperative and advanced research and instruction in many respects similar to that which one can find in the great universities of the United States.

Industrial and commercial schools are being established in Colombia. Dr. Carlos Garcia-Prada organized the *Colegio de Santander*, a technological school in which the ideal of cooperative endeavor among students and teachers is being emphasized, with the setting up of shops of all kinds—wood and

iron shops, shoemaking, etc.—thus giving a chance to the students to earn a living while learning, and the public a chance to buy goods at very low prices.

The educational reform in Colombia—in spite of the many difficulties which it faces because of lack of money—continues today with true enthusiasm. Its methods are those recommended by the great educators of the world. Its ideals are those which correspond to the universal need of bringing upon the earth a life of peace, liberty, justice, health, truth, and beauty, through the cooperative efforts of all. C.G.P.

COMENIUS, JON AMOS (1592-1670)
Comenius' place in the history of education is of commanding importance. Dr. Nicholas Murray Butler said of him on the occasion of his 300th anniversary: "He introduces and dominates the whole modern movement in the field of elementary and secondary education. His relation to our present teaching is similar to that held by Copernicus and Newton toward modern science, and Bacon and Descartes toward modern philosophy." As the "prophet of modern education" he helped lay the foundation for our modern ideals of universal, democratic education; as a practical schoolman he first conceived of a detailed,

comprehensive ladder system of schools with its Mother-School in every home, the Vernacular-School in every hamlet and village, the Latin-School in every city, and the University in every province; as a writer of textbooks he is the father of the illustrated school books (the *Orbis Pictus*); as a teacher of teachers he evolved or reaffirmed methods of instruction which have been accepted and embodied in the thinking of the world of education. Yet Comenius' work as an educator and his message for our times cannot well be understood unless it is viewed in the light of his larger purpose—the attainment of world peace based on an enlightened brotherhood of men and nations.

Comenius was born in Nivnitz, Moravia, in 1592. As a member and later a spiritual leader of the Moravians he suffered greatly in the religious persecutions that ravaged his native land during the Thirty Years' War. His wife and children murdered, his home twice plundered, and his books and manuscripts twice burned, he spent much of his long life as an exile in foreign lands. After being banished from his native land as a young minister and schoolmaster, he worked successively in Lissa, Poland, as the master of a school; in Sweden, as a reorganizer of schools; in England, in a futile attempt to interest the English in establishing an international institute of research (the *Pansophic College*); in Sweden again, as a prolific writer of textbooks for the Swedish schools; in Saros-Patek, Hungary, in charge of a school where he worked out his famous textbooks for teaching language; back to Lissa for a while, until he was again made homeless, his books and manuscripts burned, and driven anew into exile. He finally found refuge and a patron in Amsterdam where he lived until his death at the age of seventy-nine.

Comenius' principles of education are formulated in his *The Great Didactic*, in which he attempts to apply the fundamental ideas of Francis Bacon and the sense realists to the school. In applying the principle that education should follow nature, Comenius worked out fundamental principles of educational method that were later embodied in the theories of education developed in the eighteenth, nineteenth, and even twentieth centuries. Education should proceed in carefully graded steps from the easy to the diffi-

cult, the known to the unknown, the near to the remote; education is guidance and discovery, not storing the memory by rote; learning must be on the basis of understanding and interest, both to be achieved through sense perception: discipline should be mild and gentle. His principles, commonplace as they may sound to the modern educator, nevertheless were a milestone in the progress of educational thought, and saw deeply into the nature of the educational process. Comenius advocated an essentially universal and democratic organization of schools very much unlike the pattern of his time and later European development, but, in its fundamentals, akin to the present-day American ladder system. It was, however, as a textbook writer that Comenius achieved the greatest fame during his lifetime and for many years after. His educational theories were forgotten for two centuries until *The Great Didactic* was rediscovered in 1841 and republished, but his textbooks achieved immediate fame and were translated widely and used all over the world as late as 150 years after his death. (An American edition of the *Orbis Pictus* was published in New York City as late as 1810.) In these books, mostly textbooks for the teaching of Latin, Comenius shifted the emphasis in instruction from words to things, and taught language by means of pictures. The subject matter of the books was not the world of classical antiquity but of everyday, useful information and scientific knowledge. In thus teaching language as a means of expressing and interpreting the realities of contemporary moment, Comenius broke completely with the sterile traditions of *Ciceronianism* that afflicted the schools of his time and for hundreds of years after his time.

Yet it is one of the ironies of history that a man who devoted his whole life to the cause of peace and universal brotherhood should be remembered only for his contributions to educational theory and the textbooks which he prepared. It is also characteristic of the politician's state of mind, that, when he sought Sweden as a haven where he could work for the great cause which he had espoused, Comenius was advised by Oxenstierna to devote himself to the writing of text-books. "My advice," said Oxenstierna, "is that you first do something for the schools, and bring the study of the Latin tongue to greater facil-

ity; thus you will prepare for those greater matters" the program of world peace. This attitude was to be repeated three centuries later when the League of Nations turned a deaf ear to the plea that education should also be employed under its aegis as an instrument for the promotion of a new world order.

As a spiritual leader of the persecuted and exiled Moravians, Comenius did all in his power to restore them to the homeland from which they had been ruthlessly driven. If his first thoughts were directed to the education of his people, it was, as he wrote, "with no other intent but that, should God in His mercy toward us restore us to our native land, supports might be in readiness, whereby the harm wrought to our schools and our youth might be the more rapidly repaired." But he was more than a nationalist; he was a humanitarian who wished to see educational opportunities provided for "all alike, gentle and simple, rich and poor, boys and girls, in great towns and small, down to the country villages. And for this reason. Everyone who is born a human being is born with this intent—that he should be a human being, that is a reasonable creature ruling over the other creatures and bearing the likeness of his Maker." Nearly two centuries were to pass before this ideal was to be incorporated in the educational policies of nations.

Comenius was not content, however, with the provision of educational opportunities for all according to their abilities. Universal education must be informed with knowledge garnered from all the world, if universal humane education was to be disseminated. Education must become a way of light "that the young might be rescued from the mazes of the world and better instructed about all things from their very elements" and that "men's minds should be gradually raised from darkness to light and withdrawn from the vague and casual opinions to the one straightforward way of everlasting truth." He was convinced that "there is no more certain way under the sun for raising sunken humanity than the proper education of the young," and that education was to be the way to peace and to universal brotherhood.

Comenius has been described as a millenarian; devoutly religious, he could not but accept the promise of a better world. Faced with the conditions of his day, however, he

felt it his duty to contribute, so far as his powers would permit, to hastening the realization of that promise in his time. It was in this connection that he sought to turn to practical use the new knowledge which was being accumulated. With his contemporaries he shared the hope that the newly discovered sciences would, as Bacon had already expressed it, be used "to endow human life with new discoveries and resources," "to extend more widely the powers and greatness of man's estate, to secure the sovereignty of man over nature," "for the finding out the true nature of all things, whereby God might have the more glory in the workmanship of them, and men the more fruit of them."

While Comenius welcomed the new learning, he was disturbed by the threatened danger of specialization in which men would become immersed in their own immediate interests and neglect the practical contribution which could only be made by the synthesis of all the knowledge then in process of being accumulated. He anticipated by three centuries the current movement for the unification and coordination of the sciences as a tool for social progress and human welfare. This coordination of the knowledge of the world for the advancement of human welfare was to be the responsibility of an international center, a Pansophic College, a Temple of Universal Knowledge, "a structure of truth, human and divine" in which learned men would "make it the object of their combined labors to establish thoroughly the foundations of the sciences, to spread the light of wisdom throughout the human race with greater success than has heretofore been attained and to benefit mankind by new and useful inventions. For unless we desire to remain ever in the same position, or even to go back, we must take care that our successful beginnings lead on to further advances. For this no individual, no single generation sufficeth, and it is therefore essential that the work should be carried on by many persons, working in concert and using as a starting-point the researches of their predecessors. This Universal College would bear the same relation to other schools that the belly bears to other members of the body, that of a living laboratory supplying sap, vitality and strength to all."

It was not, however, the accumulation of

knowledge for its own sake in which Comenius was interested, but its unification, co-ordination and advancement for human welfare and universal peace. In expressing his hopes Comenius speaks in words of universal applicability, as vital for our own time as for the seventeenth century: "There is needed in this century an immediate remedy for the frenzy which has seized many men and is driving them in their madness to their mutual destruction. For we witness throughout the world disastrous and destructive flames of discord and wars devastating kingdoms and peoples with such persistence that all men seem to have conspired for their mutual ruin which will end only with the destruction of themselves and the universe. Nothing is, therefore, more necessary for the stability of the world, if it is not to perish completely, than some universal rededication of minds. Universal harmony and peace must be secured for the whole human race. By peace and harmony, however, I mean not that external peace between rulers and peoples among themselves, but an eternal peace of minds inspired by a system of ideas and feelings. If this could be attained, the human race has a possession of great promise."

This system of ideas and feelings could be attained through universal knowledge, which, as the foundation and coordinator of all things, would secure order and produce good rulers of states. But it would do more, if the masses would be permitted to learn and understand that the public and private welfare of all depend upon the acceptance of responsibility by each for his own proper function in life. With nations scattered over the whole world and divided by differences of languages much could be gained not only for each nation but for all peoples of the earth, if they had a common basis for mutual understanding which they could share through a common language. Such a common basis could be achieved and disseminated because of the expansion of intercourse between all parts of the world through navigation, printing and the promises of the sciences. Further, the dissemination of universal knowledge was made possible by the discovery of a method whereby all men could learn all things thoroughly (*omnes omnia omnino*). The great task for the Pansophic College would be to coördinate and unify all

knowledge and adapt it for convenient use by this method.

Comenius was not content, however, with the coordination and unification of the knowledge of the past and of his day. The Pansophic College would be concerned with emphasizing the coherence of all things, with stressing the possibilities of constant progress and with insisting on the perpetual interdependence and unification of all knowledge. Directly attacking the current belief that intellectual achievement had already reached its limits, he urged that the duty of the Pansophic College would also be to reveal the unknown areas which still remained to be discovered. Knowledge to be effective must, he urged, be universal and without any serious gaps; it must be true and sifted from the false and useless, and it must be so simplified and free from obscurities and ambiguities that it would of itself exercise an influence on the mind. The light of true knowledge would serve to promote universal knowledge and cultural unity throughout the world.

More than three centuries separate the age of Comenius from that in which we live, Comenius may have expressed his ideas in a mold which differs from ours; his faith may have been rooted in sanctions which a world, become skeptical and cynical, has questioned. We may know more of the hidden causes of things than even the optimistic age of Comenius considered possible. And yet we may well ask ourselves whether, with all the apparatus of knowledge and learning and with all the equipment of modern methods of investigation, we have advanced much further toward the realization of the hopes which Comenius entertained for an understanding world of peace and universal brotherhood. The world of the twentieth century, embroiled in constant conflicts matching in devastation and inhumanity anything even the seventeenth century with its Thirty Years War had to offer, is once more setting out on the same quest which makes Comenius as real for our day as he was for his and gives him his rightful place among those who have labored for an internationally ordered world.

COMMITTEE OF TEN (*National Education Association*). The Committee of Ten on Secondary School Studies was appointed in July, 1892 by the National Education Association on the recommendation of the National Council of Education to consider the question of establishing recognized national standards for secondary education in the United States. The committee met under the chairmanship of President Charles W. Eliot of Harvard University. Among its members were William T. Harris, United States Commissioner of Education, and James B. Angell, President of the University of Michigan.

The purpose of the Committee was to define the educational function of the public high school in the United States, and to set

up uniform standards which would govern both branches of the existing high school curriculum: preparation for college entrance, and preparation for practical life in commercial and industrial endeavors. There was great need for such a clear enunciation of secondary school purposes and standards, since the curriculum of the American high school had grown largely by accretion, and included a multiplicity of subjects poorly organized with respect to time, scope, and sequence. The general relation between the high school and college had to be defined, and an orderly pattern together with an acceptable standard for secondary education needed to be developed.

To accomplish this, the committee organized conferences on each of the existing areas of the secondary school curriculum. The following subjects were included: Latin; Greek; English; Other Modern Languages; Mathematics; Physics; Astronomy and Chemistry; Natural History, Biology, Botany, Zoology, and Physiology; History, Civil Government, and Political Economy; Physical Geography, Geology, and Meteorology. Each conference dealt with questions of scope and sequence of the subject; time allotment in number of hours per week, number of weeks per year, and number of years; uniform requirements for college entrance; methods of teaching and of examination; differentiation between pupils preparing for college and those preparing for practical life. The conferences met separately and submitted their final reports to the Committee of Ten, which then proceeded to deal with the overall picture of secondary education.

In 1893 the Committee published its report on secondary education, recommending a seemingly comprehensive and adaptable curriculum as the basis for all high school instruction. It prepared a series of model programs of study based on the list of subjects considered appropriate by the conferences. It defined the scope and sequence of courses within each subject, and the time allotment which should be accorded to each. It urged that the selection of courses remain the option of the individual high school student, so that there be an individual secondary school curriculum best suited to the individual needs of each student. It recommended that courses be rated as equivalent on the

COMMON SCHOOL MOVEMENT

basis of equal scope and time allotment.

The committee proposed that the secondary school period begin two years earlier, and that a six-year elementary school and six-year secondary school plan be adopted instead of the existing 8-4 plan. (See EDUCATIONAL LADDER.) It reaffirmed that the main function of the high school was to prepare the youth of the nation for the duties of practical life, since only a small percentage of the graduates went on to college or higher studies. In the matter of college entrance requirements, the Committee proposed that any groups of studies taken from the secondary school program be acceptable for college admission provided that there be four years of courses ranging from 16 to 20 periods each per week. The Committee also called attention to the need for better instruction in the high schools, and pointed out that this could be achieved only by providing a higher level of trained professional personnel. It therefore recommended that teachers be better trained for high school work.

The Report of the Committee of Ten had considerable influence on the development of secondary education in America, particularly during the succeeding half-century. In many instances it rescued the high school curriculum from a condition of chaotic disorganization born of the multiple accumulation of specialized subjects without regard to their overall integration. The Committee established a comprehensive and uniform standard for all secondary schools to meet, based on an articulated program of high school and college studies, and utilizing a quantitative measure of equivalent courses arrived at on a time allotment basis. Even though its suggestion that the six-year elementary and six-year secondary school plan be substituted for the older eight-year elementary and four-year secondary school plan did not gain widespread adoption, the Committee's recommendation of a reorganization of the structure of the American educational system helped prepare the way for the adoption of the 6-3-3 plan, which divided the secondary school into upper and lower units and made possible the development of the junior high school (*q.v.*). The Committee also established the policy of pupil selection of individualized programs of study, and the acceptance of all such programs by college boards as a basis for en-

trance. It thus defined the scope and function of the American high school, and laid the basis for a standardized and continuous system of American education beginning at the elementary level, and progressing through the secondary school and college.

The Committee of Ten, however, also had certain negative effects. The Committee based its standards on specified subjects, the scope and sequence of which were narrowly defined, with equivalent values established within fixed limits. As American life expanded and technological industrialism replaced an older agrarian economy, new subjects clamored for admission to the curriculum, and the equivalence, scope, and sequence of secondary school subjects had to be defined anew. The limited range of subjects recommended by the Committee of Ten became the established nucleus of a fixed and traditional secondary school curriculum which fought the intrusion of any new subject matter into the high schools. The battle of the curriculum thus became the major problem of succeeding generations that sought to adapt the high school to the changing pattern of life. How to redefine the scope, purposes, and standards of secondary education in the United States has become one of the crucial issues in curriculum development facing American education today. (See SECONDARY EDUCATION.)

COMMON SCHOOL MOVEMENT. The term *common school* is sometimes used to designate lower schools as opposed to higher schools, but it is more properly applied to such schools as are supported by general

taxation and open on a common basis to all. In America particularly it is practically synonymous with the term *public school*. As sometimes used it means only elementary or rural schools, but strictly speaking it should include all of the schools provided for by public taxation, even including the state colleges and universities. Ordinarily the term is applied to the elementary schools of a city, as distinguished from the high schools, but the decision in the the famous Kalamazoo Case of 1872 interpreted the term as covering all public schools, colleges, and universities supported by public taxation and open on a common basis to all the children of all the people.

The common school movement, then, is the movement to set up a public school system based on the principle of universal and common education for all at public expense. State-controlled and state-supported public school education today is usually universal, compulsory to a stated age level, generally sixteen, and free, although seldom common in the fullest sense of the world. The French liberalists believed that education should be universal. Roland said, "Education cannot be too widely diffused, to the end that there may be no class of citizens who may not be brought to participate in its benefits." Most of them believed that instruction should be free even for professional training and for adults. Condorcet recommended that education be absolutely free throughout. The French liberalists believed also that schooling should be compulsory and attendance obligatory. Prussia very early succeeded in getting all her children to attend schools regularly, such attendance becoming a national habit in Germany a half-century before the United States achieved a like result. Toward the middle of the 19th century, the United States, largely as a result of the opinions of our leading statesmen, the extension of suffrage, the support of associations of workmen, and the efforts of such educational reformers as Horace Mann and Henry Barnard (*qq.v.*), established free and universal education on the elementary level. This free and universal type of education was later extended upward through the secondary and higher levels, so that today we have a complete system of public education, free and open to all. Yet, although all the states have

compulsory education laws, we give each student the option of attending private schools (supervised in varying degrees by state and local education authorities) instead of the free public schools.

Although the United States has not yet actually provided equal and common educational opportunities for all, the principle of a common school system organized after the ladder pattern has been accepted as the American ideal (See EDUCATIONAL LADDER.) We believe in equal opportunities for all the children of all the people. We are committed to the principle of an education for all in common, as far as abilities and capacities permit. This is quite different from the dual system prevalent in some European countries. In Germany, France, England, and other European countries, there has been developed a dual type of education with folk schools on the one hand and secondary and higher schools on the other, schools for the "masses" and schools for the "classes", with a wide social and economic gulf between the parents who send their children to the free elementary schools and those who pay fees for their children in secondary and higher schools. The European tradition has provided for a type of public elementary school designed to serve the humble needs of a stable working class, with secondary schools and universities for the development of leaders from the more favored classes. In the United States, although at first we followed the European tradition, we have gradually evolved a common ladder type of education favoring the rise of individuals even from the humblest circumstances, minimizing all social and economic distinctions. Thus the educational system of the United States is at least more common than those of most other countries.

COMMONWEALTH FUND—See FOUNDATIONS, PHILANTHROPIC; SCHOLARSHIPS AND FELLOWSHIPS, INTERNATIONAL.

COMMONWEALTH TEACHER TRAINING STUDY. The Commonwealth Teacher Training Study, begun in 1925 by Professors W. W. Charters and D. Waples of the University of Chicago and extended over a period of three years, was financed by the Commonwealth Fund of New York City whence it drew its name. The study was made possible only by the large scale cooperation of teachers, supervisors, school administrators, and professors in teacher training institutions throughout the United States.

The purpose of the study was to make a functional job-analysis of the activities and traits of teachers which would subsequently be useful as a basis for the development of teacher training curricula. The study was carefully planned to achieve reliability from a statistical standpoint. The investigation was reported under six general headings: "A Master List of Teachers' Traits," "A Master List of Teachers' Activities," "Reliability of the Evaluations," "Using the Evaluated Activities To Revise Existing Courses," and "Using the Evaluated Activities To Construct New Courses."

The section of the study which deals with teachers' traits lists an average of 25 traits for teachers at the kindergarten, intermediate, junior, and senior high school levels. These traits are then ranked as to importance by educational experts. The final lists for the different grade levels show striking similarity.

The section of the study which deals with the activities of teachers constitutes a major contribution to the literature of teacher training. The list of teachers' activities is classified in seven divisions, as follows: (1) "Teachers' Activities Involved in Classroom Instruction," (2) "Teachers' Activities Involved in School and Class Management," (3) "Teachers' Activities Involved in Supervision of Pupils' Extra-Classroom Activities," (4) "Teachers' Activities Involving Relations With Personnel of the School Staff," (5) "Teachers' Activities Involving Relations With Members of the School Community," (6) "Teachers' Activities Concerned With Professional and Personal Advancement," and (7) "Teachers' Activities In Connection With School Plant and Supplies."

These activities were then subdivided into various sections and subgroups, resulting in a master list of activities which the investigators then sent to various educational workers

and teachers for evaluation. The master list was submitted to teachers, supervisors, principals, and instructors in education at the primary, intermediate, junior, and senior high school levels in rural and city school systems and in teacher training institutions to be evaluated on the basis of the following four criteria: (1) frequency of occurrence, (2) relative importance, (3) relative difficulty in learning, (4) value of pre-service training. Summary tables of the tabulated replies rank each activity by deciles on the basis of these criteria for the different groups and levels in the teaching profession. The sound statistical procedures utilized by the investigators assure the reliability of their findings.

The value of this entire functional analysis of teacher traits lies in its implications for teacher education, and in its direction for the construction of teacher training curriculums. The authors devote a considerable section of their report to the question of utilizing this material in the formulation of professional courses of study for teachers. They indicate how their data may be used in the improvement of existing courses and curriculums, and how their data may be utilized in the construction of new teacher training programs. They also present their own theory of the professional curriculum for teachers. The entire study is a systematic, on-the-job approach to the problem of teacher education. Its contribution in this area is one of major significance. (See *TEACHER EDUCATION*.) R.N.C.

COMMUNICABLE DISEASES OF CHILDHOOD. The major health problems of childhood and youth are the acute, communicable diseases. A disease is called com-

COMMUNICABLE DISEASES OF CHILDHOOD

municable (contagious, infectious) if it spreads from person to person, the second illness being the same as the first. Because of the prevalence of these diseases, and because the first contact usually results in infection, they are usually acquired early in life. Those persons who have been protected from exposure during childhood and who have not developed immunity may and often do acquire these so-called "childhood diseases" during adult life.

Modern methods of prevention and treatment have reduced the incidence of these diseases and the dangers of the diseases themselves and their possible complications. No infectious disease should be treated as trivial; no child should be exposed to them deliberately or because of carelessness. These illnesses produce needless suffering and, even though themselves relatively insignificant, may be followed by dangerous complications; or they may reduce general resistance so that latent or dormant infections become activated.

The close contact that is unavoidable among children in a classroom makes for the easy spread of these diseases. A running nose, a cough, fever, nausea, pallor, sore throat, or skin eruptions may be the early symptoms of one of the communicable diseases. The function of the teacher is not that of a diagnostician. Familiarity with these symptoms and an awareness of their relationship to more serious conditions should constitute part of the teacher's training equipment. An intelligent daily inspection of the pupils and the isolation of any who show any signs that may be significant of disease may prevent the development of a serious epidemic. The health of the individual school child, of other members of the school community, and frequently of the pre-school children depends to a great measure on the keen eye and alert mind of the health-conscious teacher.

Measles. The most prevalent of all communicable diseases, measles, is too often disregarded because it is mistakenly considered to be inevitable and unimportant. In the United States about 5,000,000 cases, with 10,000 deaths, occur annually. During the first three years of life, the mortality rate may be as high as fifteen to twenty per cent; by the age of ten, it falls to about one per cent and remains at this level throughout adult life. A child born of a mother who has had measles at some time during her life

is immune for about three months; thereafter susceptibility is practically universal. Except in isolated communities, permanent avoidance of the disease is almost impossible. It should however be delayed as long as possible, since the older the child the less the likelihood of serious complications. One attack usually confers permanent immunity, though second and third attacks have been known to occur.

About eight to ten days after exposure to measles, the early symptoms appear. They resemble those of a severe cold: running nose, sore eyes, irritated throat, slight cough, and moderate rise in temperature. Since the disease is apparently transmitted by droplets from the nose and mouth, this is the most infectious period of the disease, yet the most neglected. Three or four days later the characteristic reddish rash appears, first on the forehead and neck, then on the whole body. The rash lasts from four to six days and gradually fades. Measles is communicable until five days after the rash disappears.

Lung and ear complications are the most to be feared in measles, bronchopneumonia being the most frequent. Tuberculosis frequently develops in lungs in which resistance has been lowered by measles.

The protection of children against colds will also reduce their exposure to measles. Children who have been exposed to measles may be protected by the injection of any one of several available preparations: blood taken from someone who has recently convalesced from measles or who has had measles at some time in the past; or fluid obtained from the placenta after childbirth. Such injections, if given within five days after exposure, may prevent the disease; if given from the fifth to the eighth day, they will make the attack much milder.

Whooping Cough (Pertussis). Whooping cough, caused by the *bacillus of pertussis*, is one of the most serious diseases of infancy and old age. Since there is no inherited immunity, children may develop it very early in life. During the first year of life, the mortality rate may be as high as twenty-five per cent. Fully one-half of the cases occur during the first two years. The disease is serious at whatever age it occurs, for it may be followed or complicated by pneumonia and it is second only to measles in producing a predisposition to tuberculosis. In 1935 it caused more deaths among children

COMMUNICABLE DISEASES OF CHILDHOOD

of the United States than scarlet fever and diphtheria combined. One attack produces immunity.

Ten to fourteen days after exposure to the disease, the child shows the relatively mild symptoms of a cold: running nose, slight temperature, slightly sore throat, and an irritating cough. These symptoms gradually increase in severity over a period of about ten days. Then appear the characteristic attacks: a series of fifteen to twenty coughs during which the child takes in no air and usually turns blue; this spasm is followed by a sharp intake of breath which produces the identifying "whoop." The paroxysm is usually followed by vomiting. The frequency and severity of the spasms depend on the severity of the infection.

The disease is most contagious during the catarrhal period, the first ten days, and may be transmitted for a period of from six to eight weeks. This long period of communicability, lasting even after the "whoop" has disappeared, the frequently mild cases that allow the child to remain at play, and the relatively mild cases among adults in which the symptoms are not recognized but the possibility of transmission of infection is high, all tend to make it difficult to prevent the infection by preventing contacts. Although not accepted by all authorities, a vaccine has been prepared. Its use has resulted in reported protection against the disease in many children, and weakening of the symptoms in all on whom it has been used.

Mumps (specific parotitis). Mumps is a relatively mild infectious disease characterized by inflammation and enlargement of the salivary glands under the jaw and in front of the ear. The ages of greatest susceptibility to the disease are between six and sixteen. The disease is transmitted by direct contact and is communicable as long as the swelling lasts. It is practically never fatal, but is important because of a possible complicating inflammation of the sex glands in males, with resulting sterility. This necessitates rest in bed and careful medical attention as long as the swelling in the gland exists.

Diphtheria. Diphtheria is due to the rod shaped bacillus of diphtheria (known because of its discoverers as the *Klebs-Loeffer bacillus*). Susceptibility to the disease is not universal; it varies in individuals and changes with age. Most new born babies

are not susceptible, but this immunity is gradually lost. At the end of the first year, forty per cent are susceptible; by the end of the second, sixty per cent. After the fourth year, susceptibility decreases gradually so that at the age of twelve only about twenty-five per cent are susceptible. Children from two to six years old make up the majority of cases.

The germs invade the tissues lining the nose and throat, attach themselves and grow at the expense of these tissues, producing a foul, grayish membrane. The germs also produce a specific toxin (poison) which circulates throughout the body causing great damage to organs remote from the original focus: the most serious harm being suffered by the heart and the nervous system. The disease is transmitted by direct contact with the germ, either by contact with droplets from the nose or throat or with articles contaminated with the discharges: lead pencils, handkerchiefs, shared food.

From two to five days after exposure, the symptoms of a rather mild sore throat with moderate temperature appear; the patient, however, seems much sicker than he should be with such slight symptoms. The redness of the throat increases, soon yellowish spots develop and fuse to form the typical membrane. A positive diagnosis is made on finding the diphtheria bacillus in a smear taken from the membrane.

When the disease is suspected, *diphtheria anti-toxin* should be administered immediately without waiting for laboratory confirmation of the diagnosis. Earliness of anti-toxin administration is of prime importance in treatment. Anti-toxin neutralizes the dangerous effects of the circulating poison and inhibits the further activity of the germs.

The approved method of protection against diphtheria is the inoculation with *diphtheria toxoid* or *diphtheria toxin-antitoxin* of all who are susceptible to diphtheria. This susceptibility is determined by the *Schick test*. A standardized amount of *diphtheria toxin* is injected into the skin of the forearm. If an area of redness develops at the site of the injection within twenty-four to forty-eight hours, the person tested is susceptible, and needs the protecting inoculation; if the area remains normal, the injection is not needed, because immunity already exists.

COMMUNICABLE DISEASES OF CHILDHOOD

Anterior Poliomyelitis (Infantile Paralysis). Anterior poliomyelitis, a disease which attacks those cells in the spinal cord which control the nerves involving voluntary muscular activity, is apparently caused by a minute disease producing substance (a filterable virus) which enters the body by way of the nose or mouth. Although essentially a disease of children, infants are usually immune; it may attack adults. The early symptoms of the disease are headache, nausea, vomiting, and moderate rise in temperature. This may continue for three or four days, and be followed by immediate improvement or by severe headache, drowsiness or restlessness, stiffness of the neck, muscle spasms, and paralysis. The "pre-paralytic" phase may be the only evidence of infection. Except during epidemics, these mild cases may go undiagnosed; but they are as infectious as the frank cases.

There is no specific accepted preventive vaccine or serum treatment. The only valuable procedure is the isolation of normal children from contact with the general population during an epidemic.

Tuberculosis. Tuberculosis, long thought to be inevitable, is classed today among the preventable, communicable diseases, amenable to control. Previously first as the cause of death, it now occupies seventh place as far as the general mortality rates go; it is still at the top of the list for those between fifteen and forty. The cause of tuberculosis is the tubercle bacillus (the *bacillus of Koch*); there are four distinct strains of which only the bovine (bacillus of cattle tuberculosis) and the human may infect man. The bovine strain was a serious menace to the health of children who ingested it when drinking milk from tubercular cows. Careful cattle inspection, the destruction of infected cattle, and the widespread pasteurization of milk (which kills any bacilli that may be present) has made this source of infection rare. Bovine infection of children usually caused bone infection and deformities such as hump back; it also resulted in gland and intestinal manifestations of the disease. Today nearly all cases of tuberculosis in humans come from other humans and the majority are lung tuberculosis, although the tubercle bacillus can attack any tissue of the body.

Infection often occurs during infancy and

is the result, usually, of the inhalation of living tubercle bacilli which have been discharged fairly recently, and usually by means of expectoration from the body of someone else, direct droplet infection, kissing, or the use of contaminated articles. The period of incubation (interval between exposure and development of symptoms) varies tremendously. An infant may develop a generalized infection and die within a few weeks, or the bacteria may become walled off and remain quiescent for years, or even for life. The adult type of infection is due either to a re-activation of one's own dormant infection (as a result of overwork, lack of food, lack of rest, or an intercurrent infection such as measles or pneumonia) or as a result of infection with another dose of bacilli.

The early symptoms of tuberculosis are indefinite, and a diagnosis cannot be made on them alone. Loss of weight, loss of appetite, indigestion, ease of fatigability, loss of energy, hoarseness, a persistent cough, pain in the side, feverishness (particularly in the afternoon), marked sweating, and spitting of blood are all reasons for seeking medical advice. The most valuable early information is furnished by an X-ray examination; changes in breath sounds and the definite finding of tubercle bacilli in the sputum come later.

A person who has ever taken in tubercle bacilli will react positively to the tuberculin test. The test is performed by the injection of a minute amount of tuberculin (Mantoux test) into the skin of the forearm. If the area of injection becomes red, it indicates that the person has at some time been infected. This infection may be active at the time of testing, it may have occurred long ago and been completely healed; it may have been overcome without ever having produced symptoms. Those who react negatively (skin at site of injection remaining normal) have never taken in the germ, but are not necessarily immune for life. The test is used extensively in school and college groups. Those who react positively are examined by X-ray. The great majority of positive reactors are found not to have the disease; some show findings which make re-examination desirable; and a few are found to have the disease in active form. This procedure is of inestimable value in discovering early cases and sources of infection.

COMMUNITY AND SCHOOL

The treatment of tuberculosis is dependent on prolonged, complete rest, and an abundant nutritive diet. Climate is not an important factor, but treatment is best carried out in sanatoria; this is of benefit to the patient and protects those at home. Recovery is likely if treatment is begun early, as when diagnosis is made by X-ray, before recognizable general symptoms appear (X-ray evidence may be present as long as two and a half years before clinical symptoms). COMMUNITY AND SCHOOL. Realistic educators have long recognized the social and pedagogical desirability of closely relating school experiences with larger life activities. Rousseau, Pestalozzi, Spencer, and Parker (*qq.v.*) were among earlier exponents of direct experience and social realism as basic foundations of effective education. In more recent times the philosophies of John Dewey and other influential American educators reflected a critical appreciation of precisely this same necessity.

Meanwhile the increasing industrialization, urbanization, and interdependence of modern society have produced two societal developments which emphasize this educational philosophy and have profoundly affected both purpose and program of the contemporary school. These factors are (1) the decline of primary community relationships, with consequent loss of adequate opportunity for effective youth education through personal, responsible, and frequent participation under adult direction in significant community activities; and (2) the increase in both internal and international tension, strife, and breakdown which culminated in the great depression of the 1930's and the global war of the 1940's.

Thus the influence of newer educational philosophies has combined with that of disintegrating social movements to promote increasing professional awareness of the wide

gulf which exists between the teachings of the traditional school and the essential life-needs of modern youth. In consequence there is a growing agreement that school education can no longer effectively promote either individual self-development or general social welfare unless it is projected out of the cloistered classroom and into the living community, the child's primary scene of present and future life concern. Widespread interest in constructive school-community interaction for educational purposes has therefore developed during recent years.

Such thinking and experimentation as have been done in this area have channeled into at least five major conceptions of what community education should do. These five conceptions are not mutually exclusive, and, broadly considered, represent the progression of emphases developed by leading community-minded educators during the past two or three decades. Viewpoints 1, 2, and 3, it will be observed, draw the community into the school; while viewpoints 4 and 5 take the school into the community.

1. *The school should operate as an educational center for adults.* Since education is a life-long, continuous process, the use of the school plant and facilities should be available to adults as well as to children. There, in late afternoons and evenings, adults of the community should find their educational and social center wherein cultural subjects, arts and crafts, vocational training, civic forums, gymnasium, cafeteria, and the like are open to them.

2. *The school should utilize community resources to invigorate the conventional program.* In order to vitalize the curriculum and teaching methods, give depth of meaning to instruction, and provide for direct as well as vicarious learning experiences, the school should survey the educative resources of its community, catalog them, and utilize them when appropriate for its established educational purposes.

3. *The school should center its curriculum in a study of community structure, processes, and problems.* Every community is a microcosm of human experience, since within it go on the basic processes and related problems of making a living, sharing in citizenship, exchanging ideas, securing education, adjusting to people, maintaining life and

health, enjoying beauty, meeting religious needs, engaging in recreation, and the like. The core curriculum should therefore be organized around a direct study of the local and regional community's physical setting, organization, class and caste structure, basic activities, climate of opinion, and needs and problems as these and similar factors affect individual and group welfare.

4. *The school should improve the community through participation in its activities.* Students, teachers, and civic-minded laymen should cooperatively plan and execute various service projects of a genuinely civic nature. Thus youth will learn that the community has need of its service; and the community will discover that youth's contribution to the general welfare can be at once important, intelligent, and effective.

5. *The school should lead in coordinating the educative efforts of the community.* Since all life is educative, the rôle of the school in the total educational process is primarily a coordinating and a residual one. The school, therefore, should lead all the educational agencies of the community into an organized and cooperative program for the more effective education of youth and adults in school and out, and should itself provide only those aspects of a desirable education which people in such a program do not obtain elsewhere, or receive in insufficient degree.

One or more of these five approaches to community education may be found in many conventional schools, but only the Community School is sufficiently functional and versatile to utilize them all in a balanced manner. Such a school operates as a full-time educational center for the entire community population, utilizes all appropriate community resources for instructional purposes, centers its curriculum in the community itself, actively serves the locality through direct attack upon some of its pressing problems, and leads in coordinating democratically all possible community agencies toward the common goal of more effective education in that locality. This community school, historically considered, represents the second stage in "progressive education," and the third major professional orientation held by educational leaders since the turn of the present century: (1) the subject-centered traditional school, insisting upon book-knowledge-set-out-to-be-learned; (2) the

child-centered activity school, emphasizing child-interests-to-be-expressed; and now (3) the life-centered community school, stressing human-needs-to-be-met.

Experience indicates that the most successful community-centered educational programs are those which operate according to the following basic principles:

1. Distinguish three omnibus aims in the area of school-community relationships: (a) social comprehension—developing an understanding of the changing culture; (b) social motivation—establishing incentives to democratic social improvement; and (c) social skills—increasing personal competence in community participation and leadership.

2. Define the community as the service area of the school; but relate it directly and constantly with the larger areas of state, region, nation, and world.

3. Recognize three major levels of culture to be studied in every community, immediate or remote, contemporary or historical: (a) the material culture—geographic factors together with the things people have made or used; (b) the institutional culture—the mass habits or customs of the people; and (c) the psychological culture—the motivating beliefs of the people.

4. Emphasize physical setting, social processes, social structure, and social problems; and stress the close interrelationship among these factors.

5. Plan a sequential development of student experiences throughout each year of the entire school program.

6. Begin this sequence with consideration of material culture in the local community, in particular reference to its geographic and demographic aspects.

7. Expand this initial study in three related dimensions: (a) space—in other areas, geographically; (b) time—in other communities and areas, historically; and (c) scope—in institutional and psychological culture levels.

8. Utilize all appropriate techniques for effectively relating the school with the community: documentary materials, audio-visual aids, resource people, excursions, surveys, service projects, work experience, and extended field study.

9. Focus attention upon the status, problems, and social contributions of youth who have participated in the basic processes of

the various communities and societal areas studied.

10. Direct primary personal loyalties to a people's finest traditions, ethical ideals and social values, rather than to their geographic territory, political structure, or any other segment of their material or institutional culture.

Such basic principles, intelligently developed within practical programs, permit full recognition of the central tenet in the community-centered school philosophy: that education itself is inherently a social process which therefore cannot be truly realistic, vital, and defensible unless its curricular program is framed in terms of a well-pondered, first-hand acquaintance with significant aspects of the learner's physical, biological, and social environment.

COMPANY SCHOOL. A company school is essentially one that is controlled, operated, and maintained by the company for its own personnel, and refers to a variety

of training arrangements made by a company or firm for some or all of its employees. The company school (or *corporation school* or *factory school*, depending on the type of organization) is usually maintained for special groups, as for apprentices, foremen, salesmen, or office workers. The training may be short and intensive, or of a more extended nature. The instruction is given usually on the company grounds, but may be given elsewhere.

The adequacy of the company school as a means of vocational education has been criticized both favorably and unfavorably. Those who defend the company school see many advantages in having employers train their own employees. Such vocational training is likely to be more realistic than that given in some other vocational schools, which may be using obsolete machinery and processes. Since the company school is associated with an industrial plant, it is a relatively simple matter to articulate the training program with the industrial program so that the graduates of the school can step right into a job and do it well. Supply and demand of labor, too, are easily regulated because the company school can select and train only as many students as are likely to be needed. Obviously, there is little difficulty in placing the graduates since they go to work for the company that trained them.

Much of the objection to company schools comes from those who question the wisdom of the employer's supporting and controlling the vocational school. These critics object to having the school operated primarily for the employer's rather than for the student's benefit. The close relationship between school and plant does make it easier to place all graduates, but it is likely also to lead to the selection and training of students in terms of the employer's immediate needs rather than in terms of the type of training that will help most the individual student. Moreover, critics see little reason why efficiently administered public vocational schools cannot maintain such close contacts with industrial plants that the processes taught in the school are kept up to date.

The company school is operated and supported by industry because of the need such schools satisfy. As long as public vocational schools supply an inadequate number of

COMPARATIVE EDUCATION

properly trained people, industry will continue to operate schools to train the workers it must have.

F.T.S.

COMPARATIVE EDUCATION. Interest in the educational systems of foreign peoples has been manifested throughout history. One phase of the study of history of education (*q.v.*) has always been devoted to the interaction of educational theories and practices of different countries. It is only necessary to cite as an illustration the influence of European educational theories and educational practices upon the development and progress of education in the United States, and more recently of the United States upon the educational systems of other countries. During the formative period of education in the United States an extensive literature on foreign practices was accumulated in Barnard's *American Journal of Education* and later in the Reports and Bulletins of the United States Bureau (now Office) of Education. When the foundations for a national system of education were laid in England at the end of the last century and the beginning of this, Mr. (now Sir) Michael Sadler initiated the monumental series of *Special Reports on Educational Subjects*, which were published by the Board of Education and continued later in occasional educational pamphlets. Monroe's *Cyclopedia of Education* (1910-1913) included articles on education in different parts of the world. During and after World War I, interest in foreign systems and theories of education developed at a rapid rate, partly as a result of an awakened interest everywhere in international affairs generally, and partly as a consequence of the expanding concept of the scope of the study of education beyond the stage of teacher preparation.

It was on the basis of this interest that there were gradually developed in the United States, Great Britain, and Germany courses in comparative education, and an extensive literature has grown up as a result. If the history of education deals with the development of educational theories and practices and the rise of national systems in the past, comparative education is concerned with the current progress of the ideas and forces—political, economic, social, and cultural—that determine the peculiar characteristics of edu-

cation in different parts of the world.

Educational systems of national or cultural groups reflect the ideals, hopes, and aspirations of such groups. Accordingly, while the study of comparative education is concerned with such details as administration and organization, school buildings, curricula and courses of study, methods of instruction, textbooks, and salaries and status of teachers, for the student of education its primary purpose is to cultivate an insight into the meanings of the educational system that are studied. Approached from this point of view comparative education should contribute to a clearer insight into the problems of a philosophy of education built up inductively. In this way the student of education is enabled to recognize the important influence upon education of social, political, economic, and cultural backgrounds. Such an approach has become all the more necessary at a time when education is more than ever a concern of the national state, and when it is dominated by political considerations. No claim is made that educational theories and practices can be transferred from one country to another; the failure of such efforts even in reorganizing educational systems for so-called "backward" peoples may be cited as evidence. The essential contribution of comparative education as a professional study is to enrich and fructify ideas and thinking.

It is not the function of comparative education to determine whether one system of education is better than another, nor have any standards yet been developed for such determination. The word "comparative" is employed in the same way as in the terms "comparative anatomy," "comparative law," and "comparative literature."

In the development of the study of comparative education three centers have played an important role: the International Bureau of Education, Geneva, which publishes an *Annuaire International de l'Education et de l'Enseignement* (1933—); the Institute of Education of the University of London, which publishes *The Year Book of Education* (1932—); and the International Institute of Teachers College, Columbia University, which publishes the *Educational Yearbook* (1924—) and a series of studies on various phases of education in different parts of the world.

COMPENSATION. The term *compensation* is applied to the effort to hide or overcome a feeling of inadequacy, or some physical, social, or psychic defect, whether real or imaginary; and to acquire feelings of security, superiority, and social status. Strenuous attempts may be made to overcome the defect itself (direct compensation) or to develop some substitute competency or some counterbalancing or compensatory trait (indirect compensation). In its narrow technical connotation, compensation is limited to the latter phenomenon. But as ordinarily used the word includes the first meaning.

When the difficulty is attacked with extreme vigor, an excessive development of the trait being substituted may occur. This is referred to as *overcompensation* or *overreaction*.

The effort to compensate may be undertaken consciously and deliberately; or the effort may be the result of the gradual, unwitting acquisition of certain attitudes or habit patterns that may not be recognized as compensatory; or the motive may spring from conflicts that may have been completely obliterated from consciousness by the process of repression.

Compensation represents an aggressive, fighting attitude instead of retreat or surrender. Judiciously applied, it is a valuable method for overcoming personal limitations or for developing substitute proficiencies. The dogged determination to succeed engendered by a felt limitation may carry the individual to higher levels of achievement than he would reach without the "compensatory drive." Nevertheless, because it is rooted in an unhealthy soil (highly emotionalized), the compensatory drive may lead to various kinds of compensatory maladjustments, such as an exaggerated aggressiveness, a fictitious superiority complex, irrational emotionalized behavior (because the compensatory drive is unrecognized, the conflict having been repressed into the unconscious, according to the psychoanalytic theory), jealousy, belittlement

of others, fanaticism, domineeringness, rebelliousness, prudishness, arrogance (as a "reaction formation" against cowardice), delusions of grandeur or of persecution, injurious daydreaming or repressions, and various types of malbehavior. J.E.W.W.

COMPLETION TEST—See OBJECTIVE TESTS AND EXAMINATIONS.

COMPOSITION, TEACHING OF—See ENGLISH, TEACHING OF; LANGUAGE ARTS.

COMPREHENSIVE EXAMINATION.

The comprehensive examination is one which is administered for the purpose of testing the student's proficiency in a broad field of knowledge as contrasted with the usual school or college test which measures the student's ability in a single subject or in a single semester's work in that subject. Although the term comprehensive examination has been used only recently in the United States, the concept itself is much older. Most early American colleges used some form of general examination at the end of the college course, until differentiated curricula and greater freedom of choice of electives made impracticable the administration of a general examination to all students. The comprehensive examination has been used most frequently at liberal arts colleges, but modifications of the comprehensive examinations have been used at all levels from the elementary school to graduate study.

About 1930 there was a marked increase of interest in the comprehensive examination. Whitman College (Walla Walla, Washington), however, required an oral examination in the major fields by its students as early as 1913. At first the term was applied almost exclusively to an examination given to seniors to determine their standing for honors or for the baccalaureate degree in the fields in which they had concentrated their studies. In many colleges today such an examination is still given only to candidates for honors,

COMPREHENSIVE EXAMINATION

and in other colleges only certain departments require it of all seniors. Present practice does not limit to seniors the administration of comprehensive examinations; these examinations are sometimes conducted after students have completed their first two years of college work, and the results are used as a basis for determining whether these students shall be admitted to the work of the last two years.

The pattern of the comprehensive examination has been influenced by the practices of leading English universities, where this examination is of long standing. The examination may be either written or oral, or both written and oral. The questions, usually of the essay and discussion type, tend to measure not the student's memory of factual details but his ability to use, to interpret, and to apply the information he has acquired. Since the scope of the examination transcends departmental lines, the student is given an opportunity of demonstrating that he has integrated the experiences he has had in various courses and in different departments. Because of the ease with which short answer questions are used for diagnostic and comparative purposes, one part of the written examination—sometimes the entire examination—may consist entirely of objective questions.

When used at graduate schools, the comprehensive examination tends to be narrower in scope than are the usual comprehensive examinations at undergraduate colleges. As used at universities, the comprehensive examination usually is confined to the area in which the student is at work, although the examination need not be limited to the subject matter of his own department and several departments in related fields may conduct joint examinations for all students in those fields. The comprehensive examination has been used as a means of overcoming the graduate student's temptation to devote so much of his time to specialized research that he fails to see the larger implications of his problem. Many universities which do not conduct comprehensive examinations seek to serve the purposes of such an examination by their general examination for matriculation or for the degree.

The administration of comprehensive examinations has been justified as a means of maintaining academic standards and as an

instructional procedure that has educational values in its own right. Where the passing in comprehensive examinations is a requirement for a degree, it is more difficult for the inferior student to get his degree merely by passing in the required number of courses. The comprehensive examination demands of him that he demonstrate his ability to think in terms of larger problems than are discussed in any single course. His general competence in a major area is given the attention it merits as a criterion for determining his readiness to receive a degree.

In some institutions the major value of the comprehensive examination is found in its usefulness as an instructional procedure rather than in its efficacy as a test of academic achievement. The nature of the questions asked and the kinds of activities and experiences that are required in order to prepare oneself to pass in the examination are significant because they indicate to students what are regarded as desirable outcomes of a college education.

From this point of view, comprehensive examinations are valuable only to the extent that they reflect, or help formulate, a sound philosophy of education. Underlying these examinations is the basic assumption that a college education consists of more than the successful completion of a specified number of discrete courses. For reasons of academic convenience, colleges divide the study of our culture and civilization into departments and subdivide these further into courses. These subdivisions have meaning only when they are seen as parts of a larger picture, and the student's career at college is of greatest value when he is constantly integrating the experiences gained in his various college course.

The comprehensive examination seeks to demonstrate to students that they have a large share of responsibility for integrating their courses into a meaningful whole. It helps them to learn that knowledge is not so compartmentalized as the college curriculum, and that it is inadequate to look upon college work as a succession of courses that are taken, passed, and forgotten.

On the whole, critics of the comprehensive examination have objected not to the purposes which the administration of this examination seeks to serve but to the desirability

of using the examination as a means of achieving these goals. They question the wisdom of using a single examination as a means of determining whether the student is ready to receive a degree. To them the analysis of the student's entire record at college offers a more valid basis for evaluating his intellectual stature than does his performance on a single examination. Critics have challenged the assumption that the integration of the student's experiences in his various courses possesses a value distinct from the benefits derived from the courses themselves. Even those who accept this assumption nevertheless question whether the administration of comprehensive examinations helps attain this goal in the absence of thoroughgoing changes in curriculum organization and methods of teaching. From the administrative point of view, the examination is sometimes objected to because it sets up an additional requirement for a degree that may not meet with the approval of students, faculty, and members of the community. Moreover, if the examination is to assume the importance which its proponents claim, it makes heavy demands on the time of both students and faculty—time, say some critics, that may well be spent in other and more profitable ways. COMPREHENSIVE HIGH SCHOOL.

A *comprehensive* high school offers in one administrative unit, usually in one building, all the programs of secondary education provided by its community or school district. A *specialized* high school, on the other hand, offers only a part of the community's secondary school program.

The question of whether the high schools be organized as comprehensive high schools or as specialized high schools usually is not a pressing one since few communities can support more than one high school. Of necessity, most American high schools are comprehensive, with the specialized high schools found only in some of the larger and wealthier city school districts.

Where the choice between comprehensive and specialized high schools does exist, many factors enter into the judgment of preference for one or the other. The comprehensive high school is favored by those who stress the advantage of having secondary school students learn to get along with people of varying interests and abilities, the ease of transferring students from one course to another if both courses of study are under a single administrative body, the enrichment of the educational program of all students that is facilitated when many kinds of equipment are housed in the same building, and the obvious economy of joint use of such facilities as the gymnasium and the auditorium.

The advocates of specialized high schools stress the differences among the many types of high school courses and assert that each course of study can be most significant only when teachers and administrators focus their attention on the needs of students following that course of study. Moreover, many specialized high schools require expensive equipment, of which full use is not made if the majority of the students at that school are pursuing a different course of study. The proponents of the specialized high schools point, also, to the intangible value which the establishment of specialized high schools has on the student body. At a comprehensive high school, students who take an industrial course may feel that they are not so favored as are those who take the college preparatory course; when such industrial students attend a specialized high school, they can be helped to develop a pride in school and in themselves. That some educators believe specialized high schools do have much to offer to students is reflected in such a school system as that of New York City, which has a great many specialized high schools, ranging from a high school of music and art to a food trades high school. Even in that city, however, most high schools are comprehensive, some of them conducting as many as four or five different kinds of courses. (See SECONDARY EDUCATION.) J.B.

COMPULSIVE ACTS. Compulsive acts consist of uncontrollable impulses to pursue some particular form of behavior, such as touching objects in a certain order, constantly counting things, stealing, or setting fires. They frequently are associated with specific

COMPULSORY ATTENDANCE

fears or phobias (abnormal fears), serving as distractions which relieve tension, but do not eliminate the fear. Thus, intense fear of death, which may be lessened by counting objects, returns if the counting is prevented.

Since the compulsive act is the overt manifestation of emotional maladjustment, it can be corrected only by discovering and treating the emotional problem itself. Preventing the compulsive act is ineffective, since the maladjustment causing it will appear again in another and perhaps less desirable form of behavior. Furthermore, the attempt to convince the child by logical arguments that his compulsive acts are undesirable will do little, if any good, since the compulsion has no rational basis. Even if it were moderately successful, this method leaves the child with his emotional problem, and only takes from him the feeling of temporary security which the compulsive act afforded.

A clear distinction must be made between a compulsive act and a habit (*q.v.*). A habit usually can be modified without employing psychiatric techniques, because it commonly involves no deep-seated emotional tensions which are the underlying causes of compulsive acts. For example, if an adolescent boy has acquired the habit of smoking, it may be modified by any of the procedures customarily used in habit formation; e.g., he may give up smoking while in athletic training. If, however, his smoking is a compulsive act, arising from a desire to convince himself and the world that he is fully mature, ordinary methods will have little effect upon his smoking. (See FEAR; MENTAL HYGIENE.) R.V.M.

COMPULSORY ATTENDANCE. The idea that the success of a democracy can be assured only by having a literate population was so firmly accepted by early leading statesmen and lawmakers that it is not surprising to find the concept of compulsory education incorporated in the constitutions of the forty-eight states. Either through specific provision or by implication, each of the state constitutions makes provision for the establishment of a school system.

By the middle of the 19th century, it was evident that merely providing educational opportunities was not enough to insure literacy. Some means had to be found that would insure a minimum amount of education to all

the children. In 1852, Massachusetts passed the first law which required attendance at school. By 1918, all the states, including the District of Columbia, had enacted legislation requiring school attendance between specified ages. As a result of amendments and the enactment of new laws, the provisions for compulsory school attendance have been gradually enlarged and strengthened. In general, there has been a tendency to increase the minimum amount of education required of all children.

Compulsory attendance laws have not been enacted without opposition. The right of the state to compel children to attend school has been challenged as un-American in principle on the basis that such laws represent an encroachment by the state on the personal liberty of the parents. However, the right of the state to require children to receive a minimum amount of education under either private or public auspices has been upheld by court decisions.

While the educational welfare of children has been the major consideration in enacting compulsory attendance legislation, much of the progress in this direction may be attributed to the increasing financial ability of the states to provide more education and to the fact that the employment of youth has threatened the welfare of the adult worker. The extension of the compulsory attendance laws is closely associated with the child labor movement. (See CHILD LABOR.)

The effectiveness of compulsory attendance laws is dependent on a number of factors including (1) the minimum number of years of required attendance; (2) the minimum and maximum compulsory attendance ages; (3) the minimum level of educational achievement required; (4) the minimum number of days the schools are required to be in session each year; (5) the minimum number of days of required attendance each year; (6) the number of hours each day a school is required to be in session; and (7) the minimum number of hours of required attendance each day.

There is considerable variation in the provisions of compulsory attendance laws among the forty-eight states. In about two-thirds of the states, full-time school attendance is required to the age of sixteen. Children may leave school at the ages of fourteen or fifteen

COMPULSORY ATTENDANCE

in four states, and at the age of seventeen in eight states, while in six states children are required to attend school until they reach the age of eighteen unless excused for reasons specified in the attendance laws. The minimum age ranges from six to eight, with about two-thirds of the states having a minimum age of seven, although children below the age of six are permitted to attend school. The usual number of years a child is required to attend school is nine, but this varies from six in two states to twelve years in one state. In most states a child may not be exempted from the compulsory age requirement unless he has completed the work of the elementary school. In eight states, however, the completion of the work of the twelfth grade is required. In some states a child may be excused from school attendance only after reaching a certain age and provided he has completed the work of a certain grade. While a few more than half of the states require that schools be in session for at least eight to nine and a half months, almost half of the states do not require that schools be in session more than three to five months. The number of days or proportion of the minimum school term a child is required to attend school also varies among the states, as does the length of school day and the minimum number of hours of attendance required each day. (See ATTENDANCE OF PUPILS.)

Although the ideal of having every child of elementary and secondary school age attend school has not been realized, the proportion of children enrolled as well as the average daily attendance and the number of days attended each year of those enrolled has been increasing steadily.

There are a number of factors which tend to reduce the effectiveness of compulsory attendance laws. In many states inadequate finances prevent the development of an adequate educational program as well as an effective administration of the compulsory attendance laws. Specified exemptions from the mandatory requirements, however, reduce the effectiveness of the compulsory attendance laws probably more than any other single factor.

Every state permits a child to be excused from attending school if he is legally employed and is of a certain age, usually 14-16, in some states 17 or 18, and provided he

meets specified educational requirements. The educational level of achievement required of children before they can be released from attending school to engage in legal employment is set at the completion of the eighth grade in twenty-one states, the seventh grade in three states, the sixth grade in nine states, ability to read and write in seven states, while in nine states there are no specific requirements. However, in most industrial states attendance in a continuation school (*q.v.*) for a certain number of hours each day or each week is required of children leaving school to work who are under sixteen years of age and who have not completed the high school course. In some states this requirement applies to youths of seventeen and even eighteen years of age.

In order to realize more fully the ideals of compulsory education, it will be necessary in the future for some of the states to give more attention to the possibility of lengthening the period of compulsory education by requiring attendance at an earlier and to a later age, as well as to the possibility of increasing the number of days the school is in session and the number of days of required attendance during a year. In terms of attendance standards prevailing in 1935-36, the average child in one state, at the end of eight years of elementary schooling, has almost six and a half more years of education in the same period than does his cousin in another state. The possibility of establishing higher standards of educational achievement as a requisite for exemption from the mandatory requirements for the purpose of working should be considered by several of the states. All of the states will need to give special consideration to the possibility of providing (1) public relief to indigent children and/or their parents, (2) transportation for those children who do not live within a reasonable walking distance from the school which serves their needs, (3) adequate opportunities for atypical children to receive instruction and (4) more effective means of enforcing the compulsory attendance laws as well as decreasing the amount of irregular attendance. (See ATTENDANCE OF PUPILS; TRUANCY.) W.V.N.

CONCERT RECITATION. The giving of a response by the class speaking in unison is *concert recitation*. For example, children may drill on the correct spelling of a word by spelling it together orally. Concert recitation is also a common practice in the teaching of pronunciation in a foreign language class.

Those who favor concert recitation point to the fact that it gives every pupil a chance to recite and thus facilitates learning by stimulating the child to respond. The auditory response adds to the clarity of the child's impression and thus encourages learning. By letting the pupil recite as one of a chorus, the concert recitation reassures the child who is too timid to speak before an entire class.

The consensus among teachers does not favor the frequent use of the concert recitation unless it meets a specific need, as in a foreign language class or when it is modified for use in a poetry class as choral speaking (*q.v.*). Teachers find that many students learn little through the concert recitation because only a few actually do the reciting while the majority merely follow along where they are led. The learning value of speaking alone is probably greater than that of participating in a group response. Furthermore, the concert recitation favors rote memorization rather than the intelligent use of factual material.

CONCOMITANT LEARNING — See **LEARNINGS, SIMULTANEOUS**.

CONDEMNATION PROCEEDINGS.

In order to obtain property, such as sites or buildings, for school purposes, it is sometimes necessary for the educational authorities to resort to the legal process of condem-

nation. By this course the authorities appropriate the property for public use under the right of eminent domain, which recognizes the superior dominion of public use over private property. Reasonable compensation must of course be paid for the acquired property. Condemnation proceedings ought to be used as a last resort after other means, such as trying to reach agreement through conferences, have been employed unsuccessfully. C.A.D.Y.

CONFERENCE FOR EDUCATION IN THE SOUTH. This conference, whose moving spirit was the philanthropist Robert C. Ogden, began in 1898 as the Conference for Christian Education in the South. Its annual meetings brought together influential Southern leaders and Northern philanthropists and helped revive interest in public schools of the South. The conference also led to the establishment of the General Education Board, the Rockefeller-sponsored philanthropy, that was to provide in the next generation both leadership and financial support for the development of Southern public schools. H.M.B.

CONFLICTS (MENTAL AND EMOTIONAL). A *mental conflict* is a struggle between two or more incompatible urges. A state of indecision or vacillation, together with an ensuing tension and conflict, is produced when the individual must make a choice between antagonistic motives that are about equally strong, such as the desire to play ball and the obligation to prepare the written assignment. A state of conflict also arises when there is a discrepancy between the individual's desires and his capacity to achieve. The nature of the desires that clash and the resulting strain may be clearly apprehended by the individual, or the process may be more or less unconscious. Innumerable specific causes for mental conflicts exist in the complicated environments to which people must adjust: business reverses, religious qualms, political upsets, unfortunate love episodes, philosophical doubts, failure

CONSOLIDATION OF SCHOOLS

in studies or job adjustment, etc. But the most serious conflicts are created, usually in early life, by deep-seated antagonisms between the individual's egoistic desires and the social restraints imposed by the laws or conventions of society. Essentially, conflicts are socially produced.

Many conflicts are trivial and produce no injurious consequences. Properly utilized and resolved, a conflict may prove beneficial in developing initiative, versatility, resourcefulness, and a forceful dynamic personality. On the other hand, deep-seated, unresolved conflicts are often difficult to dissipate and may produce serious mental disturbances and maladjustments, such as fears, worries, anxieties, inhibitions, compulsions, inferiority feelings, feelings of shame and guilt, various abnormal physical symptoms (tics, automatisms, paralyses, palpitation, etc.), nervous maladies, mental dissociations, hysteria, and various defense or escape reactions (e.g., day-dreaming, procrastination, regression, repression, overcompensation, and malbehavior). The guilt complex in extreme cases may produce paralyzing attitudes of self-condemnation which may in turn produce further conflicts.

According to the psychoanalysts, the conflict is between antagonistic conscious and unconscious forces—between the Id (unconscious instinctual impulses craving immediate satisfaction) and the superego (a sort of overego, partly conscious and partly unconscious, that causes the ego to curb the Id, thus creating distress, neuroses, and defenses). Painful shame-producing experiences, when frequently repressed into the unconscious, produce a state of tension because the repressed desire (although forgotten because it has been rendered unconscious) is forcibly prevented from entering consciousness. According to Freud, the chief sources of the more intense emotional conflicts are sexual inhibitions and traumas, commonly dating from early life, caused by sexual perversions, repressions, or abnormal fixations of the libido (mental or psychic energy, sexual in origin) rather than by violent sexual assaults.

The sources of mental conflicts cannot be limited to the sex or power urges, however. Occasions for conflicts arise in any phase of the individual's socio-psycho-biological ac-

tivities whenever there is a lack of internal unity, integration, or harmony between the individual's desires and the demands of society.

Conflicts can be overcome by discovering and removing the causes—psychoanalytically or otherwise—by affording satisfying emotional and work outlets, by developing emotional poise, by accepting inevitable defeats with equanimity, by frankly evaluating one's problems and assuming an objective attitude toward them, by facing the world realistically, by developing beneficial compensations for personal lacks, by proper social therapy, and, in certain cases, by appropriate medical or psychiatric treatment. CONSOLIDATION OF SCHOOLS.

School consolidation involves school administrative units, fiscal units, and attendance units. There are two more or less distinct types of consolidation: (1) a combining of two or more school administrative (and often fiscal) units with no change in the location of schools or their organization and (2) a consolidating of small schools into one or more larger attendance units. The two types of consolidation may occur concurrently. School *consolidation* and *centralization* are now generally considered as synonymous terms.

American public education began as a local enterprise. This naturally resulted in many small school districts and small schools. Through consolidation, attempts are made to merge these small schools or school districts into larger units. The power to consolidate schools or school districts resides in the state legislature. Legislation may be either *mandatory* or *permissive*. Under permissive legislation the patrons of the school district, or districts, involved must first give their consent to the proposed change; under mandatory legislation such consent is unnecessary.

In the period from 1916 to 1936, consoli-

dated schools in the United States increased in number from approximately 5,000 to 17,531. From 1924 to 1938 one-room schools in the nation decreased from 165,417 to 121,178. The problem of consolidation is closely allied with that of school transportation. (See TRANSPORTATION OF PUPILS.)

The question of what the unit for school organization should be is a moot one. The tendency in recent years has been to stress the community unit as the most desirable one. The second most commonly recommended unit is the county, although there are certain political dangers inherent in making school district boundaries coterminous with those of any political, or civil, subdivision. At the present time there is one state school system (Delaware); twelve states use the county as the school administrative unit; twenty-six are organized on the district plan; and nine follow the town and township plan.

School consolidation generally leads to one or more of the following benefits: (1) a reduction of per-class or per-capita costs, (2) a greater equalization of local tax burdens, (3) a decrease in the number of teachers needed, (4) an increase in the preparation, experience, and tenure of teachers, (5) better educational achievement by pupils, (6) broader curricula, (7) an increase in the instructional time for each pupil or each class, (8) a longer school term, (9) improved attendance, (10) better school plants and equipment, and (11) greater economy and efficiency in the administration and supervision of schools.

Among the most common objections to school consolidation are the following: (1) the necessity for pupil transportation with its attendant expense and difficulties, (2) loss of the one-room school as a community center, (3) construction of new buildings or additions to present buildings, (4) increased tax rates, (5) decreased land values in the district losing its school, (6) greater danger of epidemics of disease among pupils because of the concentrated school population, (7) decrease in attention given individual pupils because of the increase in class size, (8) lessening of cooperation by school patrons, (9) need for better clothing for children to attend a consolidated school, (10) less freedom for the pupil to advance at a rate best suited to his abilities, (11) the possibility

of jealousy among the various communities comprising the consolidated district, and (12) increased danger to children's physical and moral well being because of poorer supervision during the recess periods.

Some of these disadvantages are not necessarily inherent in the process of consolidation. They may result from factors associated with school administration, guidance, teacher personnel, etc., which affect all schools and school systems, regardless of the form of organization or the size of the area served.

CONSTANT ERROR. A constant error results when any form of bias operates consistently in a testing situation. Faulty timing of a test, errors in the scoring keys or in the weighting of test parts, and failures to follow instructions for administering a test are among common causes of scores that are consistently higher (or lower) than would be obtained if the test has been properly administered and scored.

CONSTITUTIONAL PROVISIONS FOR EDUCATION — See UNITED STATES CONSTITUTION AND EDUCATION.

CONSTITUTIONAL TYPES—See TYPOLOGICAL JUDGMENT OF CHARACTER.

CONSTRUCTIVE METHOD (RESEARCH) — See RESEARCH METHODS IN EDUCATION.

CONSUMER EDUCATION. Consumer education aims at making more intelligent and discriminating consumers of goods and services. The increase in the types of goods and services available for purchase, the growing effectiveness of competitive advertising and selling pressures, the relative absence of official or authoritative evaluation of goods

and services—all these factors have led to an appreciation of the need for teaching students how to become discriminating purchasers.

While consumer education in some form has prevailed indirectly in the high schools for many years, it was not until 1929 that definite attention was given to it, and not until 1935 that a considerable number of schools taught it as a specific high school subject. The development of consumer education was given impetus by such spectacular books as those by Chase and Schlink on how the consumer is misled by business and industry. Much of the pioneer work in the development of actual courses in consumer education stemmed from the ardent interest of Henry Harap of the George Peabody School for Teachers. In general, the scope of these courses included the purchase of goods, such as food and clothing; the purchase of services, such as insurance and recreation facilities; and the making of financial arrangements, such as budgeting and installment buying.

In its earlier stages the subject was characterized by strong liberalism and even evangelism. Its introduction was favored by progressive teachers because it served as a means of emancipation from tradition both in its subject matter and in its methodology. Here was a subject of direct and immediate interest to the child, and an excellent basis for gradual improvement in the condition of the masses of people. Many of its sponsors then and now favored the use of direct materials and frowned upon more than occasional use of textbooks. Experimentation and projects in this field are generally preferred by teachers to more formal methods of instruction.

The subject is now suffering from growing pains. There is considerable conflict of opinion as to the subject area in which consumer education should be taught, and each department is making its claims. Probably more actual consumer education is being taught in home economics than in any other subject. The evidence indicates, however, that separate courses in consumer education are taught more frequently by business teachers than by others.

While the subject is far from being one of those most frequently studied in high schools, its influence upon other subjects is

great, for it has caused a consumer reorientation of most other subjects. In secondary schools the emphasis is being placed increasingly upon the consumer values of English, bookkeeping, home-making, shop, foreign language, etc. The subject has also been popular at the collegiate level, especially in the consideration of consumption as an economic phenomenon. CONTINUATION SCHOOL. Between 1918 and 1933 most of the states in the Union operated schools or classes for boys and girls of fourteen to sixteen or eighteen years of age who were employed in manufacturing and industrial pursuits. (Youth in the street trades, such as carrying newspapers, in domestic service, and in agricultural work were not included.) Generally, the aim of the continuation school was to provide a self-inventory and a stimulation of ambition for the employed minor. The schools were usually attended for from four to eight hours per week. When the instruction was of a general educational nature, the schools were known as "general continuation schools." A limited amount of the instruction given—especially to the sixteen to eighteen year old group—was of a trade preparatory nature. Although adjusted academic and vocational studies were provided, the basic functions were guidance and vocational placement.

Since 1933, compulsory continuation schools are no longer common because the minimum entrance age in most industrial states has been raised for workers in industry to sixteen or eighteen years. The New York State Regents Inquiry into the Character and Cost of Public Education recommended in 1938 the complete abandonment of continuation schools. (See VOCATIONAL EDUCATION.)

CONTINUITY TEST—See OBJECTIVE TESTS AND EXAMINATIONS.

CONTINUOUS MEASURES. Measurement of traits is regarded as falling into two categories, *continuous* and *discrete*. Discrete measurement is in terms of a real indivisible unit. For example, the numbers of pupils per class can be measured only in whole numbers of pupils. For any measure of such a trait to have meaning it must be interpreted in terms of whole numbers. Continuous measurement, on the other hand, is in terms of units that are infinitely divisible. For example, time can be measured in years, months, days, minutes, seconds, or very small fractions of a second—the accuracy of the measurement being limited only by man's ingenuity. There is inherent in continuous measurement the assumption that greater accuracy is possible. For example, stating a boy's age as eleven years implies that his age is not exactly that; in finer measurement his age would be expressed as eleven years, five months, ten days, etc.

Each continuous measure represents a range of one unit—one of the units of measurement used; there is, therefore, no gap between one continuous measurement and the next possible measurement—the measure "eleven years" begins where "ten years" leaves off. Between measures of height of 61 and 62 inches there are possible such measures as 61.01 inches, 61.02 inches, 61.03 inches, etc. (or even finer measurements). Each discrete measure, on the other hand, represents a point with a gap of one whole unit between it and the next possible measure. Between two such measures as 31 pupils and 32 pupils there is no intervening measure. The smallest possible difference between two continuous measures is infinitesimally small. The smallest possible difference between discrete measures is one whole unit. A further distinction between discrete and continuous measures is that the former are obtained by counting and the latter by measurement.

Statistical values, computed, for instance,

from a distribution of measures, must be expressed in terms that can be interpreted in a valid manner. Thus a mean or a median of discrete data must be interpretable in terms of the discrete unit in order to have meaning. Such a value as "the mean number of pupils per class in the school is 31.2" can be interpreted to mean that "if the total number of pupils in the school were distributed so that there were the same number in all classes, there would be 31 in each class with one extra pupil for every five classes." However, a median number of pupils per class of 31.2 cannot be interpreted in discrete terms.

CONTRACTS, TEACHERS' — See TEACHERS' CONTRACTS.

CONTRACTUAL LIABILITY — See LIABILITY.

CONTRIBUTORY NEGLIGENCE — See NEGLIGENCE.

CONTROL GROUP — See. EQUATING GROUPS.

CONTROVERSIAL QUESTION. Three closely interrelated factors lead inevitably to the rise of the problem of controversial questions in education. First, education cannot be carried on in separation from the major social and cultural issues of the group. Hence education becomes inevitably involved in the struggle of factions and ideas. Second, the more education becomes a responsibility of society and its main agency, the state, the greater will be the desire of the forces struggling for domination to use education as an instrument for inculcating their ideas and tendencies into the minds of youth. If these forces are not strong enough to overcome the resistance of oppositional groups, which also will try to get hold of the school, teaching has no unequivocal point of reference but becomes eclectic and often uncertain about its own goals. Naturally a society in transition with no integrating aim or tradition will create more controversial questions than a relatively stable order. Third, modern education tends toward relating the instruction of the pupil more closely to the social environment than the older forms of education. (Preparation for life; learning through ex-

CONVENT SCHOOLS

pefience; *Lebensnaehe*.) Consequently the comfortable aloofness of the older classroom from controversial issues is no longer feasible.

Different forms and conceptions of society will have different standpoints with respect to the treatment of controversial questions in the school. Orthodox societies, both political and spiritual, will tend to exclude it (religious orthodoxy, political absolutism, and totalitarianism). More individualistic, dynamic, and flexible societies will give the school a larger share in the discussion of controversial questions. Whereas the orthodox type carries with it the dangers of rigidity, crystallization, suppression and consequent revolution, the individualistic type is exposed to the peril of relativism, scepticism, and dissolution. The soundest society will be one which is capable of uniting openmindedness to new and controversial issues with firmness in essential ethical convictions. In such a society controversy, instead of leading toward disintegration, will be a means for mutual understanding and for that combination of change and stability, freedom and harmony, without which progress is impossible. CONVENT SCHOOLS. Institutions conducted by religious orders of cloistered women for the education of girls and young women of all creeds, in keeping with the educational principles of the Catholic Church and the special educational objectives of the communities controlling the schools. Such schools were a direct outgrowth of the monastic movement. Monastic communities of women developed very early and soon became "important centers of culture where the industrial arts were taught, and where books were prized, stored and multiplied." Rules for their conduct were formulated as early as the sixth century. Through the well-balanced nature of the instructional program in medieval institutions, generally including

instruction in reading and writing, spinning, weaving, and embroidery, their contribution to the education of the upper classes was significant and lasting. Many women of talent pursued their studies at higher levels and enriched the literature of the period with prose, drama, and verse of a high order. Perhaps the most notable contribution of the early convent schools was their effect on moral standards. They made it possible for girls and young women to withdraw from the worldly atmosphere of the court or society so as to secure a Christian education under the direction of cultured women. The products of such schools carried back to the court, the home, and society ideals and habits which did much to promote morality, culture, and better social conditions.

The Reformation forced the closing of schools in some European countries, notably in England and Germany, but the missionary program of the Church and the founding of new teaching orders soon opened other fields of service. Wherever cloistered or semi-cloistered communities are serving the Church today, in Europe, Asia, Africa or the Americas, instruction at various levels, elementary, secondary and collegiate, is provided by nuns with the necessary academic and professional training. The programs offered conform with local, regional, or national requirements.

The oldest convent school in the United States is Ursuline Academy in New Orleans, founded in 1727. By 1860 there were more than 200 convent schools. The programs offered during the early and middle nineteenth century included the three R's, religion, sewing, music, French, English grammar, rhetoric, literature, philosophy, history, astronomy, geography, bookkeeping, botany, geology, physiology, and penmanship. Later in the century many schools added instruction in science and mathematics. Emphasis was constantly placed on the development of proper deportment, culture, and Christian character. In a word, Catholic young women were educated "in keeping with the highest ideals of the society of the last century." Towards the end of the century, in large part because of the growing interest in college education for women, many additional subjects were added to the curriculum and elementary was separated from secondary and

higher education. Many institutions organized instruction at the college level, usually as a result of the upward extension of the secondary program. Vocational interests have been widely recognized in recent curricular changes. Programs now provide preparation on a generous scale for the occupations and professions open to women. There are approximately 700 institutions of this type in the United States (1940), mostly offering instruction at the secondary level. (See CATHOLIC EDUCATION.)

COOPERATIVE GROUP PLAN. This plan, introduced about 1925 by Dr. James F. Hosis and his associates of Teachers College, Columbia University, sets forth a new form of organization for elementary schools.

The Hosis plan divides the school into several groups. Ideally, five class groups of at least two different consecutive grades would constitute a cooperative group. The total curriculum for these five groups is divided into five different parts, and each of the five teachers is responsible for the teaching of that particular part of the curriculum to the five groups of children from the two or three grades of the school.

The main feature of the plan, the source from which the plan perhaps derives its name, is the organization of the teachers of a school into small cooperative groups, each of which is led by one of its own members, who acts as chairman. Their common interest is the pupils whom they teach. They are brought together, not because they teach the same subject, but because they have the same children. The teachers plan their work cooperatively in order to obtain the maximum of integration in the educative experiences of the children.

The cooperative group plan has been tried in a few schools, but it is probably fair to conclude that up to 1942 this plan has had little influence on the organization of elementary schools in the United States. O.G.J.

COOPERATIVE PART-TIME DIVERSIFIED OCCUPATION PLAN. In large industrial centers, it is feasible to organize cooperative education involving separate groups or classes for each trade or industrial occupation. This is not possible in the smaller cities and in nonindustrial communities. Within the last five or ten years, much progress has been made, especially in the South and Southwest, with a form of cooperative education that is admirably suited to fit young people for the diversified industrial life in those areas. This plan of instruction is called *Cooperative Part-Time Training for Diversified Occupations*. Nothing has stimulated industrial education at the high school level in many states more since the original passage of the Smith-Hughes Act of 1917 than has this form of cooperative education. It differs from cooperative education as developed in the larger cities of the North Atlantic States in that the students making up a class do not follow the same trade or occupation, but follow a variety of skilled occupations. For example, out of a typical class of fifteen students in diversified occupations, three may be employed (on an approximately half-time basis) in garages, two may work for plumbers, three may work for carpenters or builders, two may be learning to become sheet metalworkers, one an electrician, one a draftsman, two machinists, and one a toolmaker.

In so far as possible, students are grouped for their "related instruction" on the basis of the occupations they follow. When this is not feasible, it is given on an individual basis. Since the practical or trade skill part of the instruction is given "on the job," the employer supplies materials, tools, machines and other equipment. He also pays the learner a reasonable wage. (See COOPERATIVE EDUCATION.) F.T.S.

COOPERATIVE PART-TIME SCHOOL — CORE CURRICULUM

F. T. STRUCK, *Foundations of Industrial Education* (John Wiley and Sons, New York, 1930), ch. 13.

COOPERATIVE PART-TIME SCHOOL. A vocational part-time school or class is one which provides practical and related instruction to youth who are preparing for, or who have entered upon, a vocation of their own choosing. Instruction designed to enlarge the civic or vocational intelligence of the worker may be included. If the instruction is supplemental to the daily employment, it is called *trade extension education*. A special form of it is called *apprenticeship*. If, on the other hand, the instruction is for youth who have not yet entered employment, such instruction is called *trade preparatory training*—it is to prepare persons to enter the vocation.

When a program of training has been set up cooperatively, as for example between a vocational school and a labor union, or between the school and an employer or a group of employers, and especially when approximately half of the time of the school year is given over to training "on the job," then such a training program is properly known as a *cooperative part-time program*. The schools or classes involved become cooperative part-time schools or classes. F.T.S.

COORDINATION. The muscular coordinations needed for such activities as standing, walking, jumping, grasping, pulling, throwing, etc. develop gradually and are dependent upon the interaction of growth and maturation with exercise and practice. While there are decided individual differences as to the age when a child can creditably perform a specific motor activity, it is generally true that the cruder activities can be performed earlier than those requiring more refined coordination and exacting adjustment. Manual dexterity develops later than locomotor ability.

Muscular coordination arises out of varied experience and self-guidance, with direct instruction playing a minor role. The provi-

sion of space and apparatus for free play, apparatus suited to the children's level of development, plus encouragement from adults and the example of boys and girls just a little *more mature* is all that most young children need for the development of adequate coordination.

As a matter of fact, physical activities involve much more than mere muscular coordination. It is the cooperation of sense organs, especially the eyes, and the kinesthetic sense receptors in the muscle tissues, tendons, and joints, with the actions of the muscles and other bodily organs which makes possible the harmonious coalescence of the activity of muscles involved in achieving an objective. In the process of reaching and grasping, for example, the infant learns to perceive distance through his eyes more accurately at the same time that he is learning to reach and grasp with greater precision. (See PERCEPTION.) Although the emphasis in the attainment of motor skill is placed upon the rhythmic action of the muscles, the modification of behavior involves also various sense organs and relations throughout the body. Consequently, in developing coordination through practice it is necessary for the individual to concentrate upon the objective in view, or the whole act, rather than attempt to build up the unified act by attending separately to different movements in the series. When the general pattern of a motor skill has been established, then attention may be profitably turned to detailed difficulties as they arise. In other words, coordination depends upon the feeling or knack developed by the learner through varied trials, although demonstrations and suggestions may contribute, especially when offered by an instructor who is carefully observing the individual's attempts.

CORE CURRICULUM. The *Core Curriculum* generally implies a main, basic, or central course, required of all or nearly all

CORPORAL PUNISHMENT

students, in which the topics or problems are selected without regard to subject matter lines. There are two well-defined types of core curricula depending upon the criteria by which the topics or problems are selected. In one the selection by adults of essential matters for pupils to learn dominates the internal organization. This core is sometimes called unified studies (*q.v.*), survey of cultures, culture epochs (*q.v.*), areas-of-living (*q.v.*), social living, and broad-fields (*q.v.*) In the other type the problems grow out of pupil needs and are selected cooperatively by pupils, teachers, and others intimately connected with the learning group. Since this latter core approaches the experience curriculum (*q.v.*) in qualitative learning and democratic management, it is sometimes called the experience or guidance core. Most cores, however, are of the subject-matter type.

The schools have always had a core curriculum under various names and organizations. When the scope was limited, as in early Colonial days, every subject was required of everyone. As the curriculum expanded, the core in the elementary schools became the 3 R's, while the secondary school offering was divided into required and elective subjects. The new emphasis upon the core idea comes from two groups of educators: first, those who want a new essential body of knowledge more in harmony with present needs of students; second, those who want a flexible process of learning rather than a body of knowledge as the operating center. The argument for the new knowledge seems reasonably clear. Advocates of the learning process hold that it is the one aspect of education which is common to all experiences wherever found. The student who consciously controls it has a power in meeting new problems of living which the knowledge core fails to develop. Thus he is able to continue to meet life successfully after his required years in school have been completed. This concept of learning differs markedly from the point of view of teaching which has always dominated knowledge cores. As the process of learning affects the acquisition and use of knowledge, emphasis upon the process will tend to improve the scope, value, and availability of knowledge which the subject teaching lacks.

Theoretically the core should affect all

aspects of the curriculum but in practice this is not true. Pupils may have a subject or experience core for two hours and spend the remainder of the day in learning the traditional subject matter of academic subjects. The areas-of-living core reorganizes the total curriculum more than most others, but the center of organization is knowledge derived from an analysis of adult needs and activities. In practice, this has resulted in the correlation of a few required broad-fields. It is questionable whether any curriculum can have a core unless it be a flexible process of learning whatever is learned. Certainly it cannot be the same body of knowledge for all pupils, not even in exposure, regardless of the quality of learning. In the last analysis, the only real core is in the learnings which each individual accepts to live with and by, now and in the future. And it is the chief function of the school to help him make his selection of learnings as thoughtfully as possible in the light of all available personal and social conditions. (See CURRICULUM.) CORPORAL PUNISHMENT. Any punishment applied to the body and producing physical pain is corporal punishment.

History records the extensive use of corporal punishment through the ages as a reflection of a philosophy of education that asked for little more than the child's submission to authority. Although psychologists and educators object to corporal punishment in schools on many grounds, it is still used occasionally today, indicating that we have not yet wholly accepted the point of view that education is a cooperative process in which students and teacher work together to achieve desired goals.

While the school is interested in developing the child's ability to work with others and to adjust himself to the regulations necessitated by the classroom situation, it prefers the kind of pupil adjustment that arises from the child's understanding of his social responsi-

bilities rather than the instant and unquestioning obedience that is prompted only by fear of the switch. Since corporal punishment never deals with the causes of maladjustment or misconduct, it is rarely more than a temporarily effective measure that at best can only control misconduct, but not prevent it. The concomitant effects of corporal punishment have also been deplored because the use of this form of correction makes the classroom a place to be feared.

Although other forms of school punishment are still tolerated even though they may be as cruel and as ineffective as corporal punishment (sarcasm, for example), public and professional opinion is steadily increasing its opposition to the use of corporal punishment. This type of punishment has practically disappeared from modern schools; in fact, many schools have declared its use to be illegal or have prescribed detailed regulations concerning its administration. CORPORATION SCHOOL—See COMPANY SCHOOL.

CORRECTIONAL EDUCATION. In modern penology the term *correctional education* is given broad meaning. It describes all of those experiences and procedures which are brought to bear upon an individual incarcerated in a penal institution (reformatory for juveniles or adults, or a prison) for the purpose of giving him the kind of training likely to result in his being more willing and more able to live in a socially acceptable manner during and after incarceration. The extreme modern point of view sees the penal institution as corrective rather than punitive. The moderately modern point of view sees it as corrective and punitive. Hence the wide acceptance of the term "correctional education" instead of older and less meaningful terms such as "reformation," "rehabilitation," and "penal education."

Traditional education in penal institutions follows the usual patterns of philosophy, objectives, and methodology of education elsewhere. But modern correctional education breaks away from tradition in that it

looks at each individual as one who is in need of specialized educational treatment. The theory of modern penology envisions an attempt to discover through study of the whole individual (that is to say, his life history, his physical, mental and emotional makeup) what factors have been causative in his socially unacceptable past and present conduct. As a result of such study and in terms of the individual's probable future, remedial correctional treatment is prescribed. This procedure parallels that employed in the treatment of physical ailments. First, the cause of the ailment is determined and then treatment to remove the cause and cure the ailment is prescribed and applied.

Modern penal treatment is scientific and clinical in its approach. In diagnosis and treatment it directly involves a variety of specialized skills, for example, those of the penologist, physician, psychiatrist, psychologist, sociologist, biologist, criminologist, clergyman, and educator. Indirectly, numerous others are involved. It is the task of correctional education to contribute diagnostically and remedially within its sphere to the treatment process. The contribution is necessarily wide in scope. It embraces nearly all types of learnings. The approach is coordinated toward the particular purpose to be achieved with a given individual. Emphasis in approach will lie wherever indicated. The "teacher" may be anyone who is qualified for a needed approach, for example, a clergyman, a physician, a psychologist, an officer, a vocational instructor, an academic teacher, or some other. Usually, a number of "teachers" are involved, but they all know what the common objective is and what each is to do.

In practice today the theory of modern penology and, therefore, correctional education is more a trend than a reality. All degrees of perfection in practice may be observed ranging from a few gestures to very effective programs. In the correctional institution as elsewhere the success of educational processes depends upon enlightened methods, skillful teachers, and ample supplies and equipment. But here additional burdens are imposed. The very absence of constructive activity (such as purposeful education) results in anti-social education and "crime schools". People without the freedoms to which they are accustomed are emotionally

CORRELATION (CURRICULUM)

disturbed. Idle minds become sluggish or seriously affected by nostalgia. The result, first noticed by penologists many decades ago, was that a person frequently left the penal institution more vicious than when he entered, or suffering from mental deterioration. One of the first attempts to combat this outcome was an effort to introduce "education" which consisted of reading and study of the Bible and solitary contemplation of its teachings and one's own sins and shortcomings. Later, a few of the common school subjects were introduced, and then in 1870 the Elmira Reformatory was established. This institution with its School of Letters, apprentice shops, system of marks, punishments, massages, baths, and other devices, represented a radical departure from any form of penology then in practice. Its founders believed that they had found at last the sure method for successfully accomplishing the "reformation" of offenders against the law. The Elmira plan consisted of a formula which was applied indiscriminately to all. This first reformatory set the pattern for a new movement in penology which spread throughout the world and still remains in the original or a slightly modified form in many of our states as well as in foreign countries.

Modern correctional education in contrast with the original Elmira education is dynamic. It keeps pace with progress in educational philosophy and method as well as with other progress in pertinent scientific fields. It does not apply a formula for correction. On the contrary, it regards each offender as an individual who is different from all of his fellows and as such must receive individual study and treatment for the particular kind of adjustment he must make in his own community.

CORRELATION (CURRICULUM).

Correlation means the teaching and learning of essential parts of the content of subjects or broad fields which have observable relation to a common topic or theme. It is a method of unifying subject matter, but it does not necessarily represent any change in the original requirements of the individual subjects. All forms of revision of the subject curriculum move away from fragmentation toward greater unity in the essential subject matters. Correlation is at the bottom of the list of such movements since much of it is casual and incidental, being confined to the most obvious connections made by a few interested teachers. Some correlation results in greater unity through more consciously planned efforts to locate and define the more subtle relationships existing among subjects. Administrative arrangements are then made to make possible the realization of such designated correlations. Parts of art may be related to home economics for girls or shop work for boys; American literature may be taught in the same year and perhaps by the same teacher as chronological United States history; Dickens' *Tale of Two Cities* may be taught in English literature while pupils are studying the French Revolution in World History. Remedial reading courses which are prevalent in secondary schools frequently draw their materials from the texts used in other courses.

CORRELATION (STATISTICS)

Correlation is the most widely used modification of the traditional subject curriculum. For that reason it is usually designated as a curriculum although at best it can never be more than the introduction of a number of cross strands in already existing, separate and distinct, longitudinally organized bodies of knowledge. It appeals greatly to teachers since no subject loses anything. It finds favor with administrators since it does not challenge the efficiency of the authoritarian organization which is held to be one of the strengths of the traditional curriculum. Since correlation can be and generally is confined to only a relatively few subjects, it can never be a curriculum, for this term usually implies a wider and a more thorough reorganization.

Correlation is frequently confused with fusion (*q.v.*), which reevaluates old subject matter around new unifying centers. Correlated courses are also designated as integrated courses under the assumption that the clearer relationships in the new organization aid the pupil better to unify the materials in his own experiences. This point of view violates one fundamental principle of integration (*q.v.*), namely, that each pupil must break down any organization through which material is presented to him to learn and reorganize the material in terms of his own logic of experience. Thus the more thorough the unification by the teacher the more difficult is the task of the pupil to put it together around his own purposes and values, for knowledge must be functionally acquired if it is to be really and truly acquired. (See CURRICULUM.)

CORRELATION (STATISTICS). A coefficient of correlation expresses the degree to which paired items in two arrays of quantitative data vary conjointly. Thus, it has been found that husbands of high I.Q. have, on the average, wives above the mean in intelligence, and husbands of low I.Q. tend to have wives below the mean in intelligence. The degree to which the husbands' and wives' mentalities go together can be ex-

pressed numerically by the coefficient of correlation. This instance illustrates positive correlation. Conversely, students who go to the movies many times a month tend to get lower grades at school than do students who go less frequently. Since a higher score in one trait (movie attendance) is associated with a lower score in the second trait (school grades), this instance illustrates negative correlation.

The size of the coefficient of correlation varies from 0.00 to 1.00 and may be either positive or negative. It is difficult to present any definite rule as to when a coefficient of correlation is high or low since this judgment depends so much on the nature of the data. Thus, a coefficient of correlation of .60 would be low if it represented the correlation between the I.Q.'s derived by two clinical psychologists who tested the same group of children, while a correlation of .60 would be regarded as high if it represented the correlation between children's ability to sing and their scores on an arithmetic test.

Two principal uses are made of a coefficient of correlation. One is to determine the closeness with which two functions vary together, as a basis for educational practices. For example, an administrator may want to know the degree of correlation between intelligence and the ability to learn to read, so that he may judge whether classes which have been selected on the basis of homogeneity in intelligence are also approximately homogenous with reference to their ability to learn to read.

The second use is to predict standings in one function from known standings in a second function correlated with the first. The regression (*q.v.*) equation (which contains the coefficient of correlation or a function of it) may be used to predict the most probable scores of individuals in the dependent function from their known scores in the independent one. Formulas for estimating the average amount of error to be expected may be found in books on educational statistics, but there is no way of knowing how wrong the prediction may be for a given individual except within limits. Consequently, predicting success in school from an intelligence test given at entrance, based upon the correlation coefficient between the intelligence test and school marks is not without its hazards. (See PRE-

CORRELATION (STATISTICS)

DICTION OF SUCCESS.)

Though the degree of relationship between two traits may be regarded as a basis for predicting status in one trait for an individual whose status in the other trait is known, it is incorrect to assume that correlation necessarily implies causation. If the coefficient of correlation between students' scores in algebra and their scores in social studies is high, it does not mean that a student's high score in social studies is attributable to his high score in algebra. The correlation between success in algebra and success in social studies may reflect the fact that success in these subjects has a common cause or common causes, such as intelligence and good study habits.

The size of the coefficient of correlation between two traits is affected by the homogeneity of the samples upon which the correlation coefficient is based. In general, a homogeneous group will yield a lower coefficient of correlation than will a group that is less homogeneous with respect to the traits being measured. Thus, if we weighed all of the 3,500 children under fifteen years of age in an entire city, we should undoubtedly find a high degree of correlation between age and weight, for the older a child is the more does he usually weigh. On the other hand, if we were to weigh only infants who are ten days old or less, we should find a very low degree of correlation between age and weight, for many infants weigh more at birth than do other infants a few days older. It is, therefore, grossly incorrect to interpret the correlation coefficient of age and weight for infants as reflecting the degree of correlation between age and weight for children in general.

Some of the laymen's misinterpretation of correlation coefficients results from this failure to understand that a homogeneous sampling of scores yields a lower correlation coefficient than is found when the sampling is heterogeneous. Thus, in one college which prided itself on the great care with which it selects its freshmen and on the high quality of the academic work, an investigation revealed that the coefficient of correlation between intelligence test scores and success at college was $.54 \pm .03$. Some members of the faculty were disappointed, for they thought the relationship should have been much higher. What they did not realize was that

the student body was so highly selected that even the students whose intelligence test scores were the lowest in the college group would have been among the highest scorers on an intelligence test administered to all young men and women in the country. Had this college admitted all eighteen-year-olds regardless of their intelligence or scholastic status, it would soon have found that the correlation between intelligence and college success is much greater than its present study had indicated.

Varieties of Coefficients of Correlation.

There are a number of standard procedures for computing a coefficient of correlation. The basic method, used when the two variables are continuous and measured in terms of quantitative scales, is the *product-moment coefficient* (usually symbolized as r). When one of the variables is described in only two categories and yet those two categories really represent a scale the *bi-serial r* is computed. When both variables have been similarly condensed into two categories, a *tetrachoric r* is computed. When the two sets of values to be correlated are given in terms of rank order, or when the number of observed pairs of values is small and one can readily translate them into rank orders, the *rank-difference coefficient* or *rho coefficient* is commonly computed. When the two variables are measured in terms of attributes (e.g., brown eyes, hazel eyes, and blue eyes) rather than quantitative scores, a *coefficient of contingency* is often computed. In this instance we speak of the *correlation of attributes*.

Most of the procedures mentioned above assume a rectilinear regression (See REGRESSION) between the two variables correlated, in other words, a straight-line relationship or direct proportionality between the two sets of measurements. There are a few instances in educational work, particularly in connection with curves of growth and of decline in abilities, in which the regression is curved or nonlinear. In this type of case a special device known as the *correlation ratio* is employed. The *correlation ratio*, or eta coefficient, is numerically equivalent in range to the ordinary coefficient of correlation and can be interpreted similarly.

The Reliability of Coefficients of Correlation. Like all statistics—for example the mean, the median, or the standard deviation

CORRELATION (STATISTICS)

—the coefficient of correlation must often be computed for practical reasons from a sample rather than from the entire population. The reliability of the coefficient of correlation is usually indicated in terms of its *Probable Error*, which is expressed as a decimal. Thus, a coefficient of correlation which is given as $+.90 \pm .02$ means a positive coefficient of correlation of .90 with a probable error of .02. The probable error of a coefficient of correlation is interpreted as are all probable errors. (See RELIABILITY.) In the instance which has just been given, it is safe to assume that if the true correlation in the population is actually $+.90$, half of the time correlation coefficients in random samples would be between $+.88$ and $+.92$. Unless the correlation coefficient is at least 4.5 times its probable error, we cannot be very confident that even the direction of the correlation will not be changed if other samples are tested. For example, if the correlation coefficient is $+.15 \pm .08$, there is a possibility that some subsequent samples will yield a negative correlation.

Partial Correlation. Partial correlation measures the degree of conjoint variation between two variables when the influence of one or more other variables is eliminated from them both. An example is the correlation between the weight and strength of boys with chronological age held constant. The reason for desiring a partial correlation coefficient in this instance is that both weight and strength increase with age. Therefore, any immediate correlation between measurements of weight and strength among a group of boys ranging several years in age might be due to the common cause—physical maturity. Experimentally, we could determine the correlation between weight and strength for each age separately. This would require the massing of a large amount of data. Instead of following such a cumbersome and sometimes impossible procedure, we can approximate the same result by using a partial correlation formula. In order to employ this formula in the given instance, we must first compute, for the group of boys measured, the coefficients of correlation between age and weight, age and strength, and weight and strength. When only one extraneous variable is held constant we speak of a “*first-order partial r* ” and it is denoted by the symbol $r_{12.3}$, meaning that

we have the correlation between variables X_1 and X_2 with variables X_3 held constant. When two variables are held constant we have a “*second-order partial r* ”, denoted as $r_{12.34}$, and so on for high order partial r 's. It should be said, however, that rarely does the careful investigator employ partial r 's above the first order because of certain risks that the data were not properly sampled and because the intercorrelations themselves are subject to sampling errors which may be cumulative when computations are based upon combinations of them.

Multiple Correlation. Multiple correlation is the correlation between one variable, known as the dependent variable, and two or more other variables (known as independent variables) combined by appropriate weightings that produce the maximum degree of relationship possible between the dependent and the independent variables for the sampling in question. A typical instance is the correlation between some measurement of scholastic achievement (dependent variable) and several predictive indices collectively, such as scholastic-aptitude score, average high school mark, and some measure of interest or motivation. The weights to be assigned to the independent-variable measurements are customarily determined by a process of solving simultaneous equations in which the intercorrelations among all the variables are considered. The multiple coefficient of correlation is symbolized by $R_{1.234 \dots n}$, which means that the dependent variable X_1 is correlated with independent variables X_2, X_3, X_4 , on up to X_n . The multiple R is always higher than the largest correlation between any one independent variable and the dependent variable, provided that no one of the independent variables correlates perfectly with each of the others; and a variable adds little to the extent to which its correlations are high with the other independent variables or low with the dependent one. But because of the usual overlapping among the independent variables, it is found that it rarely pays to include more than three or four independent variables in the battery used to predict the dependent variable.

CORRESPONDENCE TEACHING. Correspondence teaching had its inception in the United States about 1883; and by 1941 the numbers of students enrolled in correspondence study were estimated at 800,000 in private schools and about 150,000 in public institutions (state and endowed universities and teachers colleges). It is claimed that this army of adult students enroll because correspondence teaching (1) meets needs not being met by other adult activities, (2) provides vocational training heretofore left unprovided in high schools and colleges (80 per cent of the student body take correspondence courses for vocational reasons), and (3) provides education for rural groups.

Correspondence teaching is criticized adversely because it (1) reduces the personal element in the teaching process, (2) paves the way in unsupervised institutions for fraud, (3) contributes to the formation of a maladjusted citizenry through allowing men and women to enroll for and fail in courses for which they are unsuited, and (4) absorbs 30 to 80 per cent of fees in selling costs, so that instruction purchased with the remainder is inferior. The last criticism applies more particularly to private institutions than it does to public institutions where fees are generally low and quality of instruction is relatively high. Mortality rates for discontinuing courses before they are completed vary from 12 to 53 per cent in public institutions, to as high as 94 per cent in certain private correspondence schools.

The work of most public institutions is controlled in some measure by the National University Extension Association to which most of these public institutions belong and to whose principles of ethics they subscribe. Some private institutions, realizing the necessity for improving their records, have voluntarily supported the National Home Study

Council originally begun by the Carnegie Corporation to improve correspondence teaching. This Council, a trade association, cooperates with the National University Extension Association and the Federal Trade Commission in establishing regulations for the industry; and develops standards for admission to the Council which provide a minimum of control for private organizations. The Council has approved for membership only about 45 of 350 private schools which conduct correspondence teaching. However, approximately 70 per cent of all students enrolled in private correspondence courses are registered with the 45 approved institutions.

Correspondence schools fall into several categories: public institutions, including state and endowed universities and teachers colleges; the Army, Navy, Marine Corps, Coast Guard, and the Air Corps which have used correspondence courses as a basis for promotion; quasi-public institutions consisting of industrial corporations which use correspondence teaching as a means of improving personnel; and private institutions including (a) industrial concerns which use correspondence courses as a device for selling products and (b) those controlled by individuals, partnerships, or stock companies whose purpose is making a profit from correspondence teaching.

Through such instruments as the Army Institute, which cooperates with correspondence schools in offering courses to men in the armed forces, the United States may see an extension of and improvement in correspondence teaching. Some suggestions for its improvement include a better trained field staff which will bridge the gap between the instructor and the student and between the student and his ambitions, adaptation of course materials to individual needs through a series of researches on correspondence study, and a more adequate development of adult schools and extension divisions so that correspondence schools may be relieved of offering courses unsuited to their medium.

COUNCIL, TEACHERS'. A teachers' council is a group of teachers or teacher representatives organized for the purpose of participating in the determination of educational policies of a school or a school system. The members of the council usually are elected by the teaching staff although they are occasionally appointed by the superintendent or the principal.

Although organized teacher participation has legal status in very few cities, it is a widespread city school practice which is not confined to any one section of the country or to cities of any particular size. In some cases the council consists of principals chosen by superintendents. Sometimes teachers are chosen by grades or departments, or elected at large.

While authorities generally advocate teachers' councils, a clear recognition of the council's functions is deemed essential. Discrimination between sharing in planning and assuming the responsibility for administration should be made. The principle of single-headed administration in the effective coordination of all the units of school organization is regarded as being as important as the principle of teacher participation.

The purposes set up by teachers' councils include such objectives as raising the standards of the teaching profession; improving conditions, especially financial conditions, under which teachers work; having teachers take a larger part in community affairs; con-

sulting with the school authorities on general educational matters pertaining to policies and programs; and setting up an agency which represents the teachers in the administration of the school. Nearly all phases of administration have been touched upon by these councils. The list of their achievements includes making courses of study, getting teacher-retirement laws adopted, preparing new salary schedules, revising rules and regulations of the school board, adopting teacher-rating plans, helping raise special school taxes, and consulting the superintendent concerning many school problems.

Other administrative functions in which teachers and teachers' councils participate efficiently are selecting textbooks, disciplining pupils, arranging for extension courses, handling truants and delinquents, making daily programs, making the school calendar, advancing and promoting pupils, and serving on special administrative committees. Thus, teachers participate in some functions to the extent of assuming full authority, as in making the daily schedule, while in other matters, as in preparing salary schedules, their participation is limited to making suggestions.

COUNCILS OF LEARNED AND PROFESSIONAL SOCIETIES. There are some two thousand learned and professional societies, associations, and councils that act as clearing houses for their members. Federations of associations having common interests usually refer to themselves as councils of specified learned or professional societies.

The four leading councils that directly affect the activities of educators and research workers are, in the order of establishment, the National Research Council, the American Council on Education, the American Council of Learned Societies, and the Social Science Research Council. These councils are devoted to coordinating and furthering the broader

COUNCILS OF LEARNED AND PROFESSIONAL SOCIETIES

interests of the constituent societies. They sponsor conferences and exploratory investigations conducted by planning groups from constituent and nonconstituent societies which seek to clarify issues of national importance in their field. They aid in the selection and encouragement of appropriate groups of scholars, whether or not they are members of constituent societies, to study pressing problems likely to aid in resolving issues of general concern. They act as clearing houses to study, recommend, and sponsor approved research proposals of members of the constituent societies and of small groups that often include scholars from other disciplines. The councils act for these groups in securing financial support for approved projects from business and industry, from philanthropic foundations, and from governmental agencies. They also act for the fund-granting groups in giving administrative direction and supervision to some of the projects. While these characterizations are not equally applicable to the four councils they do, in general, indicate the ways in which councils of learned and professional societies work as agents in mobilizing and focusing the energies and abilities of American scholars for advancing and disseminating knowledge.

Certain officers of the four councils meet monthly to discuss problems common to their work. Through these meetings and through the work of joint committees, the councils are able to coordinate and integrate their several undertakings.

The National Research Council was organized in 1916, with the encouragement of President Woodrow Wilson, to further national security in a world at war. Until 1919 it was a committee of the National Academy of Sciences, an agency organized in 1863 to assist the government in another war crisis. During World War I the Council worked to coordinate the country's nongovernmental scientific and technical resources and to center them on the needs of war agencies. Early in 1919 the Academy, in keeping with President Wilson's executive order, reorganized the Council on a permanent cooperative basis. It now functions through seven divisions of science and technology, a division on educational relations, and a division on relationships with international scientific organizations. The divisions of science and technology

include the Physical Sciences, Engineering and Industrial Research, Chemistry and Chemical Technology, Geology and Geography, the Medical Sciences, Biology and Agriculture, and Anthropology and Psychology.

Approximately 85 scientific and professional societies are affiliated with the Council. Their designated representatives, together with members-at-large selected by each division, constitute the working membership of the seven operating divisions. These representatives, plus an executive governing board of about 45 members, give the Council a total membership of some 290 persons. The 135 administrative and technical committees, through which the Council conducts most of its operations, actively enlist an additional 900 scientific men in their undertakings.

Financial support for war research projects which the Council arranges to be carried on by other agencies comes largely from the Federal government. The Carnegie Corporation gave the Academy \$5,000,000 to be used by the Council, of which about one-third is invested in a headquarters building and two-thirds in income producing endowment. Current research projects aggregating some \$800,000 per year are supported by specific grants from business and industry and by the subventions of philanthropic foundations. Another important undertaking of the Council has been the administration of some 1,400 postdoctoral fellowships involving an annual expenditure of approximately \$280,000. Funds for this work have been provided by the Rockefeller Foundation.

The American Council on Education was organized in January, 1918, by a representative group of educational associations. The initial purpose was to place the resources of educational institutions at the disposal of the Federal government for winning World War I, and for meeting education's responsibilities for postwar reconstruction. The Council has continued as the leading voluntary agency for co-ordinating American educational efforts through times of peace, depression, and war.

Organizations rather than individuals form the membership in the council, and are classified as constituent, institutional, and associate members. In 1942 there were 48 constituent members—national, educational organizations; 524 institutional members—colleges

COUNCILS OF LEARNED AND PROFESSIONAL SOCIETIES

and public schools; and 48 associate members—organizations having marginal interests in the Council's work. Associate members do not vote at the annual meetings of the Council; institutional members are allowed one vote, but no action is valid unless it is supported by a majority of the constituent members, each of which is allowed three votes. Responsibility for policy decisions is delegated to a nine-man executive committee which supervises administrative matters, and to a thirteen-man problems and plans committee which initiates and recommends research and other major activities.

Among the major projects of the Council during the 1930 decade were the work of the American Youth Commission, the Commission on Teacher Education, the Motion Picture Project, the Cooperative Study in General Education, the Financial Advisory Service, and the Cooperative Test Service. Other important committees are directing research or implementation studies in the relations of higher education to the Federal government, student personnel, measurement, modern languages, educational finance, accrediting procedures, school plants, educational surveys, and international relations.

Aside from receipts for annual dues of \$100 for constituent members, \$50 for institutional members, and \$10 for associate members, the Council's operating budget, which in 1942-43 was \$98,500, is derived largely from philanthropic sources. Its special projects budget, which in 1942-43 was \$670,000, is made up mostly of foundation grants, the bulk of which came from the Rockefeller and the Carnegie philanthropic agencies.

The American Council of Learned Societies is a federation of the twenty-three principal national societies devoted to the humanities and the humanistic aspects of the social sciences. These organizations, which range in age from the American Philosophical Society to the College Art Association of America, have a total membership of approximately 28,500 scholars.

The immediate occasion for establishing the Council in 1919 was to provide an organization competent to represent American scholars in the newly formed Union Académique Internationale, a world federation of national academies and councils interested in cooperative research and publication in the

humanities and social sciences. The Council operates through annual meetings to which each of the twenty-three constituent members may send two voting representatives. The annual meeting elects officers, authorizes the budget, and passes on matters of major policy. The executive committee appoints the Director of the Council, appoints committees, and acts for the Council between meetings. The operating committees are concerned with planning, implementation, project administration, emergency services, and advisory board work.

The allocation by projects of the \$695,586 in the 1941-42 budget provides an analysis of the Council's fields and categories of activity: general support and administration, \$47,635; grants-in-aid of individual research, \$14,271; grants-in-aid of publication, \$69,892; fellowships and other study aids, \$17,300; planning and developing studies in Far Eastern, Latin American, and miscellaneous fields, \$105,009; microfilming and similar research, \$128,046; concluding such major projects as Dictionary of American Biography and the Linguistic Atlas, \$33,883; conducting emergency activities, chiefly for the Federal government, including intensive language instruction, \$279,550. Funds for the budget came from the following sources: membership fees, \$835; interest on invested funds, \$1,800; sale of publications, \$11,161; individual and institutional gifts, \$10,317; Federal government, \$189,150; philanthropic foundations, \$482,323.

The Social Science Research Council was organized in 1923 to advance the scientific study of human society. The seven constituent societies that hold membership in the Council are used as means to this end. They are the American Anthropological Association, the American Economic Association, the American Historical Association, the American Political Science Association, the American Psychological Association, the American Sociological Society, and the American Statistical Association. From the beginning, the Council has concerned itself with the interests of all scholars working on social subjects, whether they were members of constituent societies or from disciplines outside the social science fields.

Each constituent member has three representatives on the Council. This group of 21

COUNTY SCHOOL SYSTEM

persons selects 9 other representatives-at-large, and the 30 persons constitute the members of the corporation and also its board of directors. The Council meets twice a year and has an executive committee that exercises all of its powers between meetings. Virtually all business clears through a committee on problems and policy, most of whose members are on the board of directors, before going to the executive committee or to the whole Council. The problems and policy committee is assisted by some twenty advisory committees and a small central staff. One assistant to the executive director of the Council is chiefly responsible for the administration of fellowships and grants-in-aid for small individual research projects.

During the decade 1923-33, grants to the Council aggregated \$4,198,000—all from philanthropic foundations, with the exception of \$80,000 received from individual donors. The major objects for which these funds were available indicate the nature of the work of the Council. In round numbers these are: general administration, \$735,000; fellowships, \$992,000; Social Science Abstracts, \$500,000; grants-in-aid, \$115,000; committees, conferences, and planning, \$395,000; special projects, \$486,000; and general projects, \$975,000. The special and general projects represent such undertakings as improving research and teaching in agricultural economics and rural sociology, population and regional studies, and a series of studies in public administration, crime, family, cultural areas, Latin-America, economic history, personality and culture, social adjustment, and social security. COUNTY SCHOOL SYSTEM. A county school system may be conceived as the

school organization embracing the territorial and civil limits of a county. It does not follow, however, that all schools are under a single county administration. A distinction must be made between the county as the basic administrative unit and the county as an intermediate unit. Under the former type of organization, all the schools, with the exception of certain independent districts in some states, are under one county board of education and one county administration. This is known as the county unit plan of organization. Under the latter form of organization, the county is an intermediate unit between the local unit,—district, town, or township,—and the state. The two forms of county school organizations are quite different in structure and function.

County Unit System. In the twelve states in which the county is the basic unit, there is a county board of education, a county superintendent appointed by the board, and teaching and supervisory staffs for all the schools in the county, except certain independent districts. Chamberlain and Meece¹ show that the county unit plan of organization is most completely developed in Louisiana, Maryland, and West Virginia. In the other nine states—Alabama, Florida, Georgia, Kentucky, New Mexico, North Carolina, Tennessee, Utah and Virginia—the organization may be described as semi-county systems, for the reason that the local districts retain some educational function and not all the schools are under the county unit organization.

In the county unit system, the county administration touches directly the beneficiaries—parents and pupils of the local communities—and may, therefore be considered as the local school system. The administration of such a system is very similar, if not identical in type, to that of a city school system. The county board and the county superintendent and his staff carry on all the functions of control, administration, and supervision in the schools of the county.

Intermediate County System. In twenty-eight states the county is an intermediate unit between the district, town, or township on the one hand and the state on the other. In these states the county school system varies greatly in structure and function, but in no case is it as thoroughly organized as in the

county unit states. In most of these states there is a county superintendent, most frequently elected by popular vote, and in some cases a county board of education. The functions of the county superintendent and county board vary from general supervision of the school but with no real authority, to fairly definite assignments of administrative and supervisory functions. There is a tendency in some of these states to shift authority from the district officials to the county officials, thus giving the county school system a more important place in the educational structure than it has had in the past.

County Aid for Education. In both district system and county unit states, the county is frequently a source of public school funds. Such county funds are usually derived from taxation of the property of the county. Mort and Reusser³ show that in 1936 there were thirty-three states which made use of the county as a source of school funds. The proportion of school income derived from county sources varied greatly, ranging from 0.3 per cent in Michigan to 57.6 per cent in Tennessee. The average for the thirty-three states was 20.6 per cent, but the proportion of school income from the counties in the entire United States amounted to only 6.93 per cent.³ (See STATE AID; SUPPORT OF EDUCATION.) COURSE OF STUDY — See CURRICULUM.

COURT, STUDENT — See STUDENT COUNCIL.

CRAFTS. *Crafts* refers to creative and productive activities accomplished by hand sometimes with the aid of simple tools or machines. *Handcraft* is also used to refer to crafts and is generally preferred to *handi-*

craft, which is now thought to convey an irrelevant implication. Tomlinson believes that the word "craft" should be understood to refer to a piece of workmanship that has some claim to beauty, and that it can be associated only with the craftsman's actual production—the work of his own hands.

Craft refers, therefore, to the transformation of materials into art form. In art education the transforming of materials is accomplished not so much for the acquisition of skill as for the sake of creative expression. Handcraft is included in the art course of study for this æsthetic purpose and because experience with materials gives the student an understanding of the ways in which they are used in industry.

The following crafts, frequently taught in elementary and secondary schools, suggest the kinds of activities that are richest in educational possibilities and implications: modeling, pottery making, plaster working, cement and concrete working, carving, bookmaking, costume-making, toy-making, printing, wood-working, textile weaving, metal working, and photography.

Craft work may grow out of the children's experiences in the art period, in other subject areas, or even in their out-of-work life. In any case, the crafts may and often do become the center of interest in the entire school curriculum and may at such times receive major emphasis. L.L.W.

CREATIVE EDUCATION. Creative education is the name given to the training which first finds and then preserves and strengthens the native artistry in each of us. It places emphasis on the education of individuality; it searches, therefore, for gifts of self-expression, gives them both ready reception and necessary exercise in a favoring environment, and offers also the professional direction to insure the full and normal development for a strong individuality adjusted to effective social living.

In youth education the creative approach is

CREATIVE EDUCATION

based upon several assumptions: that the young are naturally—but not always openly—creative, inventive, individualistic; that, since they are little conditioned by traditional thinking and feeling, they are curious about truth and eager to explore it; that if permitted, the young are daring and active in recording individual responses; further, that they become enthusiastic workers on projects self-conceived or accepted wholly as worthy—in other words, that youth begins by being a unique and capable interpreter of life and must be treated and respected as such.

This is the artist's equipment whatever the medium, and the scientist's also, the possession of a stubborn respect for one's individual interpretation of what is seen, felt, thought, and desired. It arises out of that enduring stuff of personality possessed by each of us which distinguishes us, indeed, from every other human creature until, as the years go by, group pressure and conventional living force us into the common mould. Creative education, however, presents the view that this distinguishing individuality, the creative spirit, never really dies but may be rescued at any age and reinstated into its rightful place of control; it affirms also that when neglected, misjudged, or mismanaged, the creative spirit may harden into dark and evil practices—which makes creative education imperative, especially in the earlier years—but we have abundant evidence that fundamentally it prefers the good and may be led by friendly nurturing along the path of truth and light.

That path to the recovering and strengthening of the better creative personality, whether for youth or for adult, is through natural and enjoyable self-expression. This may take a thousand varied forms: writing and the arts, story telling and the recounting of vivid experience, dramatic expression, the interpretive dance, free discussion, conversation—a long neglected art—imagining, planning, thinking—one of the highest of the arts—inventing, constructing, exploration and research.

Outstanding in the method of teaching is a good reception for every offering however crude or however slow in developing, provided that it is a decent and sincere expression of individuality. The professional guide would know that at this point the urge to

create is more important than the product, that the urge, indeed, is more important than the pace. He would know also that when strong interest in self-expression is kept alive among the young over a long period of time, there is a marked advance in social adjustment: posture and movement become noticeably more mature, speech rapidly approaches adult standards of communication, and group behavior takes on a closer resemblance to the code of well-bred adults.

To meet youth on this level of understanding, creative education demands leaders who not only comprehend the sources and uses of the creative urge but also those who have never lost touch with their own unique creative spirit. Continuous experience as a creative individual is the qualification supreme for those who hope to guide creative youth.

A further assumption of creative education is that self-expression under professional guidance is not only a form of learning—the modern phrase is, "We learn by doing"—but also that it offers the essential exercise for the healthy growth of taste. Higher discriminations and appreciations are notable outcomes of guided creative effort.

Heretofore in the non-quantitative matters of the spirit, measures of the value of method or of outcome have never been wholly dependable. However, we now have significant proof of the effectiveness of creative procedures through the long researches of J. Wayne Wrightstone and his group working under grants from the General Education Board and the Works Progress Administration. (See his *Appraisal of Newer Elementary School Practices*, 1935, and his *Appraisal of Experimental High School Practices*, 1936, Teachers College, New York.) Students of conventional schools and students of experimental schools, in strictly matched pairs, were tested in information, school skills, organization of material—all the types of ability that could be considered even remotely a product of school study.

In the conventional schools which the Wrightstone group examined, the course was kept to the curriculum and the single text book; all the members of the class studied the same lessons; recitations were heard and quizzes were given—the usual procedure of traditional learning. In the experimental classes, however, there would be a dozen text

CREDIT

books and a library to draw from; the course ranged far in and out of the boundaries of a fixed curriculum; group and individual projects replaced the assigned lesson; discussion took the place of the recitation; and drawing, graph, poem, play, and story were accepted as a welcome sign of the outpouring of strong interest. Thus the creative spirit was openly invited to suggest, fabricate, invent, explore, and adventure in learning.

In the Wrightstone tests the schools that gave full opportunity for creative self-expression win on practically every count. Their students recalled more "facts" although they had "studied" less; they knew better how to find needed data; they organized their material better; and by test in every subject of study, including biology, chemistry, physics, algebra, geometry and Latin, they were more skilled than their conventional fellows who had labored without the fun and the rich excitement of creative learning. In the elementary schools, similarly tested, the children who had been taught by project, environmental explorations, and healthy self-expression were never outclassed, not even in the so-called fundamentals.

The creative approach to learning, which is an encouragement of initiative in thinking, feeling, and in written, oral, graphic, and constructive self-expression, is now an obvious characteristic of elementary education in the United States, and it is rapidly becoming a noticeable feature of secondary education. An outstanding example of the latter may be found in Wilford M. Aiken's *The Story of The Eight-Year Study* and the four other volumes of *Adventures in American Education* (Harper's, 1942). Here is the story of how students and teachers working together reexamined critically the objectives of secondary school instruction, formulated new procedures, reshaped content to meet the needs of today and tomorrow, and, through free use of the native gifts of initiative, judgment, and imagination, created a new and measurably superior instrument of education for high school youth.

Both partisans and critics of the European and American "activity school," of which creative education is a natural offspring, seem often to suggest an irreconcilable conflict between traditional learning and an education aimed primarily to develop independent,

creative personalities. Creative education, however, is simply another method of learning; it does not seek either to oppose or to supersede instruction in factual knowledge but, rather, it offers an additional, and more effective, approach. When guidance in self-expression is at its best, for example, the demand for factual instruction is often greater than the supply. It takes possession of the learner and sets him ranging far and wide; research begins, even in the primary grades; libraries and neighboring institutions are probed; friends and family are relentlessly interrogated for assistance; and often nearly all the waking hours of the student are given over to the shaping and perfecting of the idea or thing which is the eventual product of creative effort and desire. The significant contribution of creative education is that it has put the tools of learning into the willing hands of youth. H.M.

CREDIT. Credit is a quantitative measure of the work done by a student in high school or in college. Credit has been expressed in a variety of units. Basic to all these units is the *unit*, which has been used for years in high schools and which refers to a school subject taken for a year and meeting five times a week. Upon the basis of taking four subjects each year for four years, the pupil secures 16 units of credit; this has been a commonly accepted basis for graduation from high school. The term *credit* refers, frequently, to a subject taken for half a year and meeting five times weekly; high school graduation would require 32 *credits* and thus two *credits* equal one *unit*.

Colleges express credit in terms of hours. The *semester hour* of credit is secured by taking a subject that meets once a week for a semester; if it meets five days each week for

a semester, it carries 5 semester hours of credit; 5 semester hours are, therefore, the equivalent of a *credit* as defined above. Upon the basis of carrying three subjects meetings five days each week, or five subjects meeting three days each week for each of the four years in college, the student earns 120 semester hours, the typical requirement for graduation. Colleges and universities that operate upon a quarterly basis use the *quarter hour* instead of the *semester hour* and thus 45 quarter hours instead of 30 semester hours will be secured each year; 180 quarter hours, therefore, would be required generally for graduation. Because of specific course requirements, the total number of semester or quarter hours required for a degree are generally greater than 120 and 180 respectively. Two semester hours are the equivalent of 3 quarter hours.

The matter of equivalence of credits is being severely criticized. It is claimed that no two semester hours are the equivalent of any other two semester hours and that, therefore, it is nonsense to speak of two semester hours as being equal to three quarter hours. Critics claim that these units fail to measure growth and therefore are valueless; they insist that we must have some means of determining what effect the course has had upon the student. Does the student have useful information? Is he able to use this information? Has he related this information to his previous and other concurrent experiences? In other words, has growth taken place? The critics say that in theory we accept growth as a goal of education but that in practice we are content with allowing the student to pile up credits. It must be recognized that credits tell a limited story; they tell the amount of time spent in classes in which the student did at least the minimum of work demanded for the granting of credit. That minimum might have been no more than regular class attendance.

Four attacks are being made upon the problem of equivalence of credit (1) Certain colleges give weighted credit in terms of the quality of the work done. Thus, work of *A* quality may receive more than regular credit, whereas work of *D* quality receives less than regular credit toward graduation. (2) Other colleges require a certain average quality of performance such as an average

of *C*, as well as the required number of credit hours. (3) Some authorities are urging the abandonment of the credit system and the adoption of a comprehensive and lengthy examination requirement, both written and oral, that would show more accurately the effect of schooling upon the individual. (4) The Eight Year Study of the Progressive Education Association (*g.v.*) points in the direction of abandoning grades and credits for courses, and of providing experiences, broad in scope, that are evaluated constantly during the student's school life.

What finally becomes accepted practice with reference to describing what a pupil has done during the period he spends in a given school will affect greatly the whole problem of the evaluation and transfer of credit. Present practices in this respect tend to be too routine. Standards are set and rules applied. Where certain schools are on the approved list, students are transferred without question. In some instances a rule automatically reduces the amount of transfer credit allowed. In other instances, all transfer credit below a certain quality (grade) level is denied. Such practices as these ease the administrative problems created by students who transfer from one institution to another, but they assume a nonexistent universal equivalence of credit.

Good admission practice considers at least the following procedures: ". . . adequate information should be at hand regarding the standards of institutions previously attended, supplemented by careful studies of the success or failure of other transfers from the same institutions; and as much information as possible should be obtained about the individual student himself and his reasons for transferring [from another institution]."

CRITIC TEACHER. A critic teacher is usually regarded as a regular teacher who has special responsibility for the supervision of one or more student teachers, apprentice teachers, or internes who are assigned to the school of the critic teacher. Sometimes the critic teacher is responsible to both the teacher training institution and the school system; under another plan the critic teacher is virtually classified as a supervisor with little or no regular teaching responsibility. (See STUDENT TEACHING; TEACHER EDUCATION.) R.F.B.

CRITICAL ATTITUDE. A critical attitude distinguishes the educated from the uneducated man. It also distinguishes advanced from primitive civilizations. Whereas the first fosters critical thinking, the latter generally consider critical scrutiny into the causes of events to be sacrilege. Signs of such an attitude can be found even today; many people are reluctant to make a critical examination of their own habits, customs, and mores.

But it would be one-sided to consider a certain degree of distrust in criticism as a sign only of superstition, of laziness, or of a tendency of those in power to keep a state of society, profitable to them, stable. This distrust springs sometimes from the observation that a critical attitude alone, without being complemented by constructive ideas, and corresponding action, may create scepticism and cynicism and be more disintegrating than productive. It is, furthermore, often easier and less courageous, to criticize than to believe and do something. Hence a person as well as society in which criticism prevails over faith is as much in peril as one in which criticism is not dared or forbidden.

Education, therefore, must help a child to build up so much confidence in his own self and in the value of life that a critical attitude, which must also be evoked, does not disintegrate his personality, but helps him in the search for truth and in the development of

well examined and voluntarily acknowledged loyalties. Here lies one of the most responsible and subtle tasks of the educator, for which no recipe can be given. It requires on the part of the educator most of all personal experience, psychological insight, and a mature philosophy of life. R.U.

CULTURAL RELATIONS, DIVISION OF (U. S. Department of State). The Division of Cultural Relations of the Department of State seeks to develop between the United States and foreign peoples that reciprocal understanding essential to harmonious political relationship and to the most effective cooperation in peace and war. Its principal objectives are improved mutual understanding; the removal of barriers to cultural intercourse; and the promotion of a free interchange of thought and achievements through scientific, educational and technical advancement, the arts and the press, motion pictures and radio, and visits of leaders in the various fields of knowledge. The creation of the Division, in July 1938, followed by slightly more than one year the ratification by our Government of the first official step toward an improved mutual cultural understanding among the peoples of this Hemisphere; namely, the Convention for the Promotion of Inter-American Cultural Relations, agreed to at Buenos Aires in 1936.

In 1938 an Interdepartmental Committee on Cooperation with the American Republics was also created in Washington. This Committee was established at the instance of the President to examine the subject of cooperation with the other American republics, and to prepare a concrete program for rendering

CULTURAL RELATIONS, DIVISION OF

closer and more effective the relationships between our people and their neighbors in the other American countries.

A separate section, originally set up in the Division of the American Republics of the Department of State to handle the administrative details connected with the work of the Interdepartmental Committee, has been transferred to the Division of Cultural Relations. This section also handles the loan of civilian experts and technicians from United States Government agencies to assist the Governments of the other American republics at their specific request. Such assistance has ranged from improvements in immigration procedure, customs tariffs, and statistics, to matters of commercial policy, taxation, monetary problems, fishery research, boat operation and child welfare.

The work of the Division of Cultural Relations in general is not geographically restricted to this hemisphere. The Division is carrying on a comprehensive cultural program in China, for instance; and is furthering cultural relations in many regions of Asia, Africa, and Europe. However, especial emphasis has been laid in the important field of inter-American relations.

The principal activities of the Department of State through the Division of Cultural Relations are as follows:

1. The travel grant program for persons of influence in the professions, education, arts, and sciences, which aims at a diffusion of understanding and mutual knowledge between the Americas through the establishment of personal relations between intellectual and scientific leaders. The constructive results cannot be immediately apparent at the start since they depend on a gradual dissemination of ideas among the most influential persons and groups in each of the countries represented. It is hoped, however, that through a cumulative process of friendly contacts any existing barriers of cultural isolation will be reduced.

2. Travel grants to professors, to satisfy requests from universities in other countries for the services of professors from the United States, and vice versa. The United States Office of Education, with which the Division cooperates closely, has official responsibility for handling negotiations regarding professor and student exchanges at this end.

3. Travel grants to students to overcome

one of the principal obstacles to a larger flow of students between the United States and the other American republics—the cost of travel. These grants are awarded to supplement fellowships or scholarships granted by universities which afford the most liberal treatment as regards scholarships or fellowships.

4. The administration of the Convention for the Promotion of Inter-American Cultural Relations, providing for a token exchange of students and professors among the ratifying countries. Fifteen of the twenty-one American republics have ratified the convention, and over seventy awards have been made since January 1940.

5. Cooperation with the cultural institutes established in the other American republics, principally by nationals of those countries, to promote closer cultural relations with the United States. The cultural institutes are located in the principal cities of the other American republics and constitute important local centers of intellectual interchange. In the light of recent international developments, these cultural institutes are being strengthened by cooperation and some financial assistance with funds furnished by the Coordinator of Inter-American Affairs. Most of them now provide sponsorship of radio programs, concerts, lectures, and exhibits; engage in the organized teaching of English, and, in some cases, of Spanish and Portuguese to resident Americans; maintain a library of United States books and magazines; offer hospitality to visiting citizens of the United States; aid in the selection of students for travel and study in the United States; publish bulletins of activities; and advise United States students working in the other American republics.

6. The interchange of books and publications between the United States and other countries.

7. The widespread distribution of suitable educational and documentary motion pictures—a program of growing importance and of great value in reaching large groups of people.

8. In the field of radio, cooperation with the international broadcasting companies on cultural programs; cooperation with national and other broadcasting companies and institutions in the United States on programs about other countries; and cooperation with

Government agencies in the preparation and planning of cultural radio programs and projects.

9. Supervision of the cultural relations officers recently appointed to many of our diplomatic missions. These officers are members of the Auxiliary Foreign Service and their primary function is to assist the head of the mission in matters of cultural significance and to keep the Department of State informed of local developments in the cultural field.

C.A.T.

CULTURE-EPOCH THEORY. The early educational psychologists believed that the human race in its development has passed through certain stages or periods which the unfolding life of the individual repeats, both physically and mentally. This theory, as applied to mental development, was designated by the Herbartians as the "culture-epoch theory," and by the biologists, in its application to physical development, as the "recapitulation theory." The culture-epoch theory was accepted and elaborated upon by G. Stanley Hall as a basic principle of educational method. Hall was firmly convinced that "ontogeny repeats phylogeny" (the development of the individual recapitulates the development of the race) in the mental life as well as the physical. The teacher must discover, through the study of anthropology and genetic psychology, the stages in the mental development of mankind, and then so construct the curriculum and so build methods that the growth of the child will follow a natural order of development. He urged educators to "develop nature's first intention and fulfill the law of nascent periods, or else not only no good, but great harm, may be done." These nascent stages or periods were the times at which the child was ready to assimilate new types of materials because of changes in his nature. Thus in the first grade, when the child is in the savage state, he should be devoting his time to a study of the American Indian so intensively that savage life is reconstructed with reasonable completeness. In the second grade, when the child has passed into the nomadic stage, pastoral life must be the theme; the reading, music, oral discussions, manual activities, and the number work must now concern themselves with the activities of the nomad. Year by year, the child comes closer to the age in which he must

live, (the simple agricultural stage to the simple handicraft stage to the modern complex industrial and commercial age). By retracing the stages of social development, the curriculum unfolds itself in complete harmony with the child who is, by his very nature, taking the same path in his own development.

The culture-epoch theory was applied particularly by teachers of elementary-school history in the organization of the history curriculum. This theory has been largely rejected because of the findings of more recent psychological studies and investigations. Give the child of seven a choice between two toys, an oxcart and an airplane, and he will most likely not choose the oxcart, for which the culture-epoch theory would claim he had a natural affinity.

CURRICULUM. Theoretically, and more and more in practice, the term *curriculum* is used to mean the students' total learning activities or experiences that take place under the direction of the school. This point of view, coming rapidly to the front during these past few years—an era of intensive school modernization in this country—stands in marked contrast to the original conception of the curriculum, one which limited the term to the particular program of studies that a student followed in the school.

This broadening of the term has come about naturally to serve the educator's emerging appreciations that child growth is a total process rather than merely a mental process, that the whole school program rather than just the classroom procedure holds these growth possibilities, and that people learn through active participation rather than through passive assimilation of subject content. As long as assign-study-recite was an accepted formula for the greater part of child development, the curriculum could be

CURRICULUM

conceived as those courses or subjects that were lined up for the student to take; but as soon as the theory of mental discipline was discarded and the belief in "whole child" learning began to be realized in practice, the curriculum became as broad as the total program of activities that were to serve the child while under the guidance of the school.

As long as the classroom program and the curriculum were accepted as somewhat synonymous, then the school used the term *extracurricular activities* to designate those activities carried forward by the school outside the classroom. That these were actually considered something secondary and not a legitimate part of the school's activities has been indicated by the common practice of denying the student active participation in a number of them unless his scholarship in his class work was maintained at a level good enough to designate him as "eligible."

Because of the earlier view of the curriculum as only the classroom program, the 1930-1940 period of so-called curriculum reorganization must go down in the educational records as primarily a course-of-study building period, the courses of study having been turned out by the thousands for the various subjects in an attempt to improve the school through the subject approach to reorganization. So intensive was this movement, it has been estimated that as many as half of the schools and school systems of the country either built or borrowed courses of study, or at least had teacher study committees at work considering their classroom offerings.

Curriculum reorganization of this type became so technical during the period that some curriculum theorists classified the multitude of attempts into a few distinct types of approaches to the task. For instance, the adult-needs approach, if adopted, would lead the school and its teacher committees first to study adult needs and then to set up appropriate course offerings and practices. Other approaches were based on a socio-economic or a child-needs criterion.

Gradually these technical intricacies of school curriculum reorganization have lost their hold, and the problem of curriculum reorganization is now looked upon not as a mechanical task to be engaged in for a specific period of time in which a pattern would be developed by the master strategists to be

handed down as a guide for all teachers, but rather as a day-by-day improvement of the learning situations to be carried on by each teacher and each staff member of the school as long as he continues in service. However, the need for leadership is not minimized in this shifting of approaches.

With this more flexible conception of school modernization at hand, curriculum building becomes instead curriculum development. That is, the curriculum is not a framework of courses, subjects, and other activities to be determined entirely in advance and installed in the school prior to the time the teachers and the students come together; the curriculum is a constantly changing and emerging frame of reference, to be felt or sensed in a school rather than a thing to be mechanically manipulated. The real educational leader does not build a curriculum for his school—he provides for it.

There is now discernible a promising tendency in the secondary schools, as in the elementary schools, to distinguish, though not too sharply, between general and specialized education. The interest in the distinctions reveals the educator's concern today for educational goals, for no one would ever worry about such differences in offerings and activities unless he first had had in mind the purposes of the school's program.

General education is that part of the student's complete program that is being experienced by the whole group, so desirable do the curriculum planners consider it as training for the common life—for the common good—for general citizenship. For example, if the school asks all students to take United States History, then this subject must be considered as a part of general education. As distinguished from such a course, but not necessarily opposed to it, there are the specialized courses selected by individual students to meet particular needs. For instance, Latin, stenography, chemistry, orchestra, and a multitude of others stand out as specialized courses.

There has been a tendency in recent years to merge or to relate subjects and courses formerly offered independently. *Correlation*, *fusion*, *integration*, and *core* courses (qq.v.) are among the terms that have been used in this connection. This tendency has been particularly apparent in the area of gen-

eral education. Educators are re-examining and re-emphasizing their goals in the area of general training for life. It is no surprise, then, that such subjects as English, social studies, general or consumer mathematics, and art appreciation are losing their identity in core courses of a broadened and enriched nature. Since the study of English and mathematics results from the need for English and mathematics in everyday social affairs, surely these subjects are related to the social studies. This relationship gives point to the numerous attempts to eliminate artificial subject barriers in curriculum development.

The educator who draws his distinctions in general and specialized education, and thus sharpens his focus upon his goals, is just as cautious in not merging unrelated subjects as he is eager to eliminate artificial distinctions. For example, in the case of Latin, algebra, geometry, vocational machine shop, typing, and many other subjects of the specialized nature, it is apparent that efficiency of instruction asks that they retain their separate-subject distinctions. And, in the area of general education, when the educator sets out to teach a group to live better with their neighbors in the community, the course that results may be a half-day program that replaces and draws upon such former separate courses as English, community civics, general business training, general science, general mathematics, and art and music appreciation. Guidance, self-government, and similar features of the whole school program may also be drawn into this general course.

How these newer attitudes toward the curriculum are modifying school practice can best be seen from a study of the experiences which schools have when they attack the problems of curriculum construction from a modern point of view. The so-called core curriculum (*q.v.*) for example, can never be typed or described so definitely as a subject can be. For this reason it is unwise to point out a specific core course as the pattern to be followed. However, a student of this movement in secondary education would do well to study the various programs that have sprung from this concept during the past eight or ten years. There are the programs of that small group of California high schools known as the Co-operating Schools; the core

courses in the Denver public schools; those in the junior high schools at Springfield, Missouri; the work in the Norris, Tennessee, school; the core courses that are operating in the Tulsa, Oklahoma, schools; the courses under way at the Highland Park, Illinois, High School; the various combination courses that were developed by the schools in the Eight-Year Study; and hundreds of other examples.

A typical example of the workings of the core concept is that given of the Norris, Tennessee, program, in HAROLD SPEARS, *The Emerging High School Curriculum*. A description of this program as it was operating follows:

The organization of learning experiences up to the eleventh year follows the core plan. The key teacher of a core course is known as the core teacher and may come from any subject field. An English teacher may serve as the master teacher for the seventh-grade and eighth-grade group, a social studies teacher for the ninth-grade, and a science teacher for the tenth-grade. This plan of teacher assignment is possible, since the scope of the core is quite flexible, the experiences are drawn from many fields, and the services of the other teachers of the school are available in the progress of any one of the core programs.

Each class group in the high school, at the beginning of the school year, discusses and plans with the teacher the subjects or problems around which the work of that group will revolve for the year. The staff of the school feels that, given half a chance, students will no doubt choose areas of learning as least as valuable as those the school might set up. This planning period may extend from two weeks to a month. The basic activities of everyday life are taken as the point of departure in the planning. Bus trips to typical communities in the Norris area have been found helpful in this exploration, as have the findings of study groups elsewhere which have attempted to determine these basic activities of everyday living. Out of this study period comes the selection of the program to be followed.

The core program of the seventh-grade and eighth-grade group extends throughout the day. The center of interest is co-operation, and the students find action and give service

CURRICULUM

to the school through what is known as "the co-operative." Experiences and study grow out of services rendered the school through the cafeteria, the school bank, insurance, truck gardening, a supplies and candy store, and a lost-and-found department. The master teacher guides the group, with others from such fields as art, home economics, and agriculture coming and going as the work progresses. As in all groups, the emphasis is as much upon the democratic way of working as it is upon individual outcomes. As the studies of the students grow out of their co-operative activities, it can readily be seen how such specifics as written and oral expression and mathematics find their place in the course.

The ninth-year group spends three hours of the day under the guidance of the master teacher, with other teachers assisting. This core has absorbed the work formerly handled in the fields of science, English, and social studies. In the direction of the course, the obligation is to the student's needs and interests, both social and individual, and not to the former subject fields. It is necessary each year, for example, to devote considerable time to reading with understanding, writing legibly, and spelling correctly.

One year a section of the ninth-grade group selected the conservation of human and material resources as the year's topic. Out of this grew a specific interest in game control and the scientific use of land. The group was given permission to use and experiment with a typical tract of Tennessee land, approximately 100 acres, at the edge of the town and near the school. Co-operating in the development of this tract of land is the Forestry Relationships Department of the Tennessee Valley Authority. The whole program was developed around the project, one step leading naturally into another. Science, social studies, and English experiences became functional. Following the co-operative plan the Norris School endorses, the original class divided into five smaller groups, each responsible for the handling of twenty acres. Experiences out on the land would lead the groups back into the classrooms and the science laboratory for study.

The land, much of which was wooded, was surveyed from many angles. Each group, through its survey and follow-up work in

school, has a fair conception of the economic value of its section. Forest control and game control lead off as topics of interest. The wild life of the tract, both plant and animal, afford natural topics for study. Each of the five groups, in the handling of its section, has before it the possibilities of raising food to care for the animal life, harvesting the nut crop, producing food for human consumption, providing grazing land, and even harvesting the lumber. Chemistry, biology, economics, English, agriculture, forestry, and a dozen other former specialized courses grow naturally into one as this core course progresses.

The problems of the South formed the work of the tenth-grade core for one year. Out of the broader topic came intensive study of rural electrification and diseases of diet deficiency. Like the ninth grade, this group is under the direction of a core teacher for three hours, other teachers being called in as needed. Former subjects replaced include English, social studies, and science. At any time in the progress of the core course, provision is made for special interests of smaller groups growing out of the broader topics.

Students move freely in and out of the classrooms and laboratories of the Norris School, as their work leads them here and there. No teacher considers this an infringement upon his own rights, for the pupil and not the subject is the focal point. The science laboratory is really a laboratory. At any period of the day as many as a half dozen groups from various classes may be found there at work. Since this is the accepted procedure, it does not disturb the regular science work. It is the regular science work.

As part of her contribution to the core program, the English teacher handles the written and oral reports of trips and experiments. Each student has an individual record folder for these reports. An error chart is also kept in the folder. For the sake of individual needs, a part of the English work has no particular connection with the core experiences. The reading program, for instance, may go beyond the core program.

The topics chosen in the core program lean heavily toward the social-studies field, but, as has been indicated, other implications, such as the scientific, are given free

CURRICULUM, ENRICHMENT OF

play. The eleventh-grade and twelfth-grade social-studies courses, like the core courses in the lower years, provide for pupil selection of problems. No subject is necessarily taught from year to year. In one year the topics covered were as follows: tenth year, origin of modern civilizations; eleventh year, food and consumership; and twelfth year, county government and safe driving. Consumership provided special studies for small groups of students, of such commodities as soap, hats, and shirts. Manufacturing companies and others worked closely with the class in supplying materials, products, and other teaching aids, even sending materials to be tested by the students in the school laboratory. The drugstore of the town assisted in these tests, both with materials and with testing devices. In the government study, county officials gave the school full cooperation in the project.

The next year the following topics were selected by the classes: tenth year, problems of the South; eleventh year, international problems, crime, and housing; and twelfth year, labor, education, and safe driving. The Safety Service of the Norris Properties Division is co-operating in the teaching of driving to all seniors, not only in the techniques but in the actual experience. A representative of the state government will give the examinations and will grant drivers' licenses to those eligible.

This account of the Norris, Tennessee, program exemplifies the meaning of the statement that when subjects are no longer given major emphasis in the area of general education, areas of living or other centers of interest close to the here-and-now existence of the students find their place in the curriculum pattern. (See ACTIVITY PROGRAM; AREAS OF LIVING; BROAD-FIELDS CURRICULUM; CORRELATION (CURRICULUM); CURRICULUM, ENRICHMENT OF; FUSION; INTEGRATION; MINIMUM ESSENTIALS; UNIFIED STUDIES; UNIT PLANNING AND TEACHING.) CURRICULUM, ENRICHMENT OF.

There are two distinct conceptions of enrichment of the curriculum in operation in American schools. In the first and most widely used one, enrichment refers to the new subject matter and materials added to the usual content of subjects in order to increase the students' understanding of the basic material to be learned. Such subject matter and materials may come from within or without the field in which the subject is located. Regardless of the source of new materials, some points are reasonably clear. The control in the selection and organization lies with the teacher or someone representing the school authority. The basic subject matter of the subject is a rarely modified constant. The purpose of such enrichment is to improve the method of teaching such basic subject matter by removing some of the original formality. The new materials are used to improve the pupils' knowledge or understanding of these basic materials, not to make them more immediately valuable or functional. This distinction is important since the improvement of functional value would in many instances destroy the selected and organized basic materials. Illustrations of enrichment are the use of visual aids, plays, excursions and varied types of pupil activities in or out of school. (See such articles as AUDIO-VISUAL AIDS; DRAMATIZATION; TRIP, SCHOOL.) Two contributing factors in the movement for enrichment were (1) the increasing recognition of individual differences in pupils' abilities and interests, and (2) the inadequate achievement of pupils in the basic materials. This point of view of enrichment is dominant in educational practice.

A second but less understood conception is that enrichment refers to a continuous widening of the area of experiences of pupils in the surrounding culture in order that they may be better able to find their real problems, to set their directional guides, and to determine a desirable plan of action. The

problem represents a disturbance in the psychological field arising out of constant interaction with the environment. Enriching experience through wider movement in the environment expands the psychological field, causing many and varied problems to arise. Thus, choices of problems for study must be made which in turn implies control of the process of improving value judgments. Under these circumstances, (1) the control is with the cooperative group, (2) the purpose is to find out what experiences are worth studying and to study them intelligently, (3) the basic continuity is in the improvement of the process of intelligent social action, (4) the learnings are immediately functional in the operating experience. Use is also made of visual aids, plays, excursions, and many other types of pupil activities. The chief purpose of such enrichment is to aid pupils to improve the quality of their living in and out of the school through increasingly intelligent behavior in meeting everyday situations.

CUSTODIAL CARE. The school janitor occupies an important place in the school system. Upon him rests the responsibility for the care and custody of the school building, equipment, and supplies, for keeping the building ready for community use and in condition to safeguard the health of teachers and pupils, and for maintaining the external con-

ditions necessary for effective learning. To a large extent, the school janitor determines the standards for the care of the school building; he is mainly responsible for favorable or unfavorable impressions of the public with respect to the physical aspects of the school.

The janitor is responsible for sanitary conditions of the schoolroom, toilets, grounds, and water supply. It is his duty to provide proper ventilation, and to keep the building at a uniform and even temperature. He removes fire hazards, clears ice and snow from the walks, washes windows, adjusts and repairs window shades, and performs hundreds of similar duties which keep the school in smooth running order. He should be well mannered and personally clean, and it is essential that he should have good moral character.

One of the most important duties of janitorial service is the cleaning of classrooms. Most regulations governing janitorial service specify that classrooms shall be cleaned after the close of the afternoon session of school. Corridors and stairs are cleaned usually between periods during the school day, and special rooms are cleaned at any time they are not in use during school hours. Frequency of cleaning depends to some extent upon frequency of use. Halls and corridors should be cleaned at least twice a day, and most classrooms once a day. The time required to clean a classroom depends upon the type of floor, the kind of interior finish, and the variety and character of equipment. The cooperation of teachers and pupils in keeping the building clean can save much time for the janitor. If the school building is to be cleaned properly, adequate manpower and proper cleaning materials and equipment must be provided. The janitor-engineer should know the best types of equipment and the best materials, agents, and treatment to use in his work.

It is obvious that the position of school janitor should be occupied only by a person who understands the duties to be performed and the fundamental facts about health and sanitation. In spite of the recognized importance of janitorial service, however, progress in this branch of service has lagged behind progress in other phases of school work. Although the tendency is definitely in the direction of improvement of janitorial service—

through increased salaries, specialized training, and greater security—the typical janitor is nevertheless a person with little or no specialized training and with inadequate general education. Frequently he is old, overworked, and underpaid.

Pioneer work in training of janitor-engineers and custodians began in Minneapolis. Attention is now being given to the problem throughout the country. Many cities have instituted training courses for this type of work, and Missouri has a state-wide training system carried on under the auspices of the State Department of Education, with centers in the

cities and teacher-education institutions. In some other states, universities and colleges now provide training courses for janitorial service.

DAILY ASSIGNMENT — See **ASSIGNMENT**.

DAILY LESSON PLAN. A plan prepared by the teacher in advance of a class meeting, the daily lesson plan is a guide to the content to be treated and the procedures to be followed during the lesson. In present-day practice the daily lesson plan is a plan of the activities to be carried on during a class period, rather than a lesson to be recited.

Investigations indicate that teachers are required to prepare written daily lesson plans in fewer than fifty per cent of our schools. The requirements for such plans vary from mere outlines of topics to be taught to detailed explanations of the particular items to be treated. Among the items comprising written lesson plans are the following: aims or objectives, outline of subject matter to be covered, learning activities or exercises, methods and techniques to be used, assignment for the day, and reference books to be used by the class.

There seems to be little uniformity in the arrangement or the order in which these items are put in the plans, except for the common practice of stating the aims or objectives at the beginning of the plan. Some teachers use the parallel column form (usually two columns), with the subject matter or topics in one column, and in the second column the learning exercises and methods to be used. In many schools which require plans, teachers are supplied with plan books that provide a small space for each class for each day of the week. Such plan books usually contain little more than outlines of the subject matter to be covered and actually should not be designated as plans. A good lesson plan contains at least four items, namely, the objectives of the day's work, the learning experiences and content through which the objectives are to be attained, the methods and special techniques to be employed, and the assignment.

Many teachers and administrators regard the daily lesson plan as a symbol of the subject-dominated school because of the implied assumption that it is the teacher who must decide in advance what is to be discussed in class as well as the order in which the various questions are to be taken up. In any school where the curriculum (plan) is viewed in a more modern manner, the planning of the day's activities is a co-operative responsibility which concerns the students as well as the teachers. Criticism has been raised also to the implication that the daily lesson is the unit of learning and that the child's experiences at school can be planned in terms of a series of discrete lessons, each with its own objectives and procedures.

It is such objections as these which have led to the changing concept of lesson planning. Emphasis is being placed increasingly on planning not in terms of single lessons but in terms of the larger units and experiences. The lesson plan, moreover, is not treated by the teacher in the way a physician regards a physician's prescription. The lesson plan guides without dictating; it is highly flexible; and it is adaptable to the particular needs and problems, anticipated or unforeseen, that arise in class. The detailed lesson plan made according to a rigid outline that tended too often to limit classroom procedures and to place undue emphasis on subject matter at the expense of pupil needs, is being replaced by more flexible plans which recognize the aim of the teacher's preparation as being the more effective guidance of his students' experience. (See also **DIARY, CLASS**.)

DALCROZE — See EURYTHMICS, DALCROZE.

DALTON PLAN. Helen Parkhurst introduced this plan in the school system of Dalton, Massachusetts, about 1920. Her concept of teaching was at variance with the traditional practice of that time; her innovations are embraced in the *Dalton Plan*.

The heart of the plan is the mimeographed or printed *contract* which constitutes the work for a school month of twenty days, and the contract in turn is composed of daily portions called *problems*. A contract relates to some large topic or division of a subject, e.g., the study of China in geography, with the problems as subdivisions of the topic. Some of the problems are given weights of two days' credit while others receive half a day's credit. These problems specify the readings, questions, maps, written work, and other exercises that must be completed for the pupil to get credit. After completing one or more problems, the pupil indicates on the room graph after his name just how much he has done; by this means the teacher can keep track of his pupils' progress. Since the pupil has his own graph, he knows also how far he has gone in each subject covered.

Budgeting of time is also involved because a pupil is free to move from room to room and to stay with one subject as long as he desires, provided he does not neglect other subjects. There are no bells announcing periods. Scheduled meetings of a class occur about once a week; these periods are devoted to debates, socialized discussions, or other important matters demanding the attention of all class members.

The emphasis upon the planning of the contract is probably the chief contribution of the plan. Working out the learning exercises leading to the attainment of aims in the general topic for the month requires more teacher foresight than making a daily assignment. Correlation between the subject fields demands faculty cooperation. Attempts are made to link the contract with the preceding one, and to use and locate "pockets of interest."

While the plan has been used widely, it has not been copied in its entirety, but it has been modified to fit circumstances. The freedom to move about from one class to another or to continue working in one class-

room has been generally eliminated. Correlation of subject matter may or may not be achieved. Instead of being a school innovation, the plan may be used by only a few teachers in the school.

The contract method of teaching includes the contract as a label, but the artificial block of work for a school month has often been discarded as have been the portions for daily work. Rather, the contract takes on the characteristics of what is now called the *unit*. It is a shift from the daily assignment to the consideration of a large topic or problem. It is also a shift from highly individualized activities to social or group activities. This treatment includes the objectives to be attained, the learning exercises, and the guides for study.

In the original Dalton Plan the contract was mimeographed or printed, and each pupil received a copy. The time devoted to the contract varied according to the ability of pupils and the nature of the topic under consideration. Provisions for individual differences were met by additional projects or undertakings for bright pupils. So much has been incorporated in the concept of *contract* that it can mean just what a teacher wants to read into it. One writer has suggested that the term be discarded because there are other more appropriate labels, such as *unit* (See UNIT PLANNING AND TEACHING), which describe better the kind of teaching in progress.

DARTMOUTH CASE. Constitutional limitations against State legislative control over private institutions of higher education are illustrated in the famous Dartmouth College case. In 1769 King George III of Great Britain granted a charter to Dartmouth College. In 1816, the New Hampshire Legislature adopted two statutes, without the con-

DAVISON FELLOWSHIPS — DAYDREAMING

sent of the Trustees of the College, which would have altered the charter in material respects including changing the name, the selection of trustees, and the control of the property. In a proceeding to recover the College books and property, in which the College was represented by Daniel Webster, the Supreme Court of the United States led by Chief Justice Marshall held the legislation unconstitutional as abrogating Article I, Section 10 of the Constitution of the United States which forbids any state from passing any law impairing the obligations of contract. Since the crown charter was in the nature of a contract between the King and this private corporation, the constitutional protection applied to it. *Trustees of Dartmouth College v. Woodward*, 4 Wheat. 517-715 (U. S. 1819).

The practical effect of the case, which is an important one in constitutional law, has been weakened by a general practice since used by states at the time of granting charters to reserve the right to amend or revoke charters, as well as by later decisions of the Court in extending the powers of the state to control certain types of corporations.

DAVISON FELLOWSHIPS — See SCHOLARSHIPS AND FELLOWSHIPS, INTERNATIONAL.

DAY NURSERY. A day nursery is a place where mothers may leave their children during the day while they are away at work. The aim of the day nursery is primarily to give physical care and protection to young children of working mothers.

When the industrial employment of married women reached a peak of three million in 1930, the number of day nurseries increased until in 1931, there were about 800. Most of these are in the industrial centers of the East and Middle West.

The nursery school (*q.v.*) is to be distinguished from the day nursery in that the former is primarily an educational institution with pedagogical methods and objectives, whereas the day nursery often provides only physical care; though, of late years, some day nurseries under institutional agencies have been expanding their services by introducing kindergarten and social case work.

M.E.F.

DAYDREAMING. In daydreaming, reverie, or fantasy (also phantasy) an individual attains satisfaction through the imaginary representation of experiences not achieved in reality. Daydreaming is common among both children and adults. It may occur as the result of inhibiting the play of self-centered children who have failed to develop active interests. An inappropriate curriculum may also contribute to daydreaming; the dull child does not comprehend what is going on and the bright child is not challenged, hence they resort to reverie. Generally there is more daydreaming during adolescence, probably due to an increase in problems of emotional adjustment at this period.

The most frequent use of fantasy at all age levels is as a form of compensation for, or escape from unpleasant reality. This is shown in the content of daydreams, which may be classified either as the "suffering hero" or the "conquering hero" type. If the individual feels that he is unfairly treated, he may imagine himself to be a suffering hero or martyr who is the object of pity and sympathy. If opportunities for a reasonable amount of self-assertion are denied him, he may resort to the conquering hero fantasy wherein he pictures himself as an important personage or hero receiving the plaudits and adulations of the multitude.

Daydreaming as creative imagination is constructive, especially in art, music, drama, and literature. It may also contribute to adjustment by reducing emotional tension. Fantasy may have recreational value, too, if the person attending a movie or reading a story identifies himself with the characters. Daydreaming is serious only when it is used excessively and becomes a substitute for real accomplishment.

It is important that every individual be taught to expect some failure, to face it squarely, and to make daydreams come true. (See ESCAPE TENDENCY; MENTAL HYGIENE.)

DEAF, EDUCATION OF THE. The education of the deaf has made great progress during recent years. Not so very long ago, the deaf were legally classed with idiots, usually confined to institutions, and generally referred to as "deaf and dumb" or "deaf mutes." Today, educators are aware that the deaf are a group of people with the same range of intelligence as hearing people and, given the proper educational opportunities, they will be useful citizens, economically independent, and competent to direct their own affairs.

Types of Deaf People: There are two types of deaf people, those who lost their hearing after having acquired speech, and those who either were born deaf or lost their hearing before language had been established. People with normal hearing have language and speech, not because they were formally taught, but because they imitated first sounds, then words, then phrases, until finally, they could enunciate whole sentences. To this group, language is indeed a gift! To the group handicapped at an early age by deafness, the acquisition of language is a long, laborious process.

At a Conference of Executives of American Schools for the Deaf, the following definitions were prepared and adopted:

The Deaf: Those in whom the sense of hearing is nonfunctional for the ordinary purposes of life. This general group is made up of two distinct classes based entirely on the time of the loss of hearing; the congenitally deaf—those who were born deaf; the adventitiously deaf—those who were born with normal hearing but in whom the sense of hearing became nonfunctional later through illness or accident.

The Hard of Hearing: Those in whom the sense of hearing, although defective, is functional with or without a hearing aid.

Causes of Deafness: About fifty per cent of the population of the average school for the deaf is made up of congenital cases. The remaining cases are due to such adventitious causes as meningitis, mastoiditis, birth injury, and the infectious and contagious diseases of childhood. The amount of hearing loss is not standardized by cause. The congenitally deaf may be profoundly or only partially deaf. This is true, also, of the adventitiously deafened.

Testing: The group audiometer makes possible the testing of groups of forty at a time. It is simple to administer and to interpret. Pupils who are screened out with this test as having some loss should be given an individual test.

A decibel is the smallest amount of sound that the normal human ear can distinguish. The pure tone audiometer is an individual testing machine and makes possible a graphic picture of one's hearing loss. This picture is called an audiogram. The tones usually tested are 64 (middle C), 128, 256, 512, 1024, 2048, 4096 and 8192. These tones are called frequencies. The tonal range of the human voice as used in speech is, for the most part from 300 to 3,000 frequencies. For educational purposes, the audiogram in this speech range is most indicative. An average of hearing sensation units or decibels loss on the frequencies 256, 512, 1024, 2048 and 4096 is called the speech hearing loss.

What Hearing Loss Requires Special Education? If the hearing loss is sufficient to retard normal progress in the usual school, the child requires special education. When studying a case, one must consider, in addition to the pupil's other defects (the diseases that ravage the hearing often leave some other physical defects), his emotional stability, social adjustment, general intelligence, and school record. The school record may show retardation or behavior difficulties. A careful study of the physical, mental, emotional and educational history will usually indicate whether the child is able to make satisfactory progress and adjustment in a regular school. As a rule, a loss of fifty decibels indicates the need for special education.

With a hearing loss of fifty or more decibels in the speech tones, it is important that the child receive special handling educationally. In the large classes of normal children, the severely hard of hearing pupil is lost because of the garbled speech sounds that reach his ear and the weird interpretation he gives them. The child who does not hear the initial or final sounds of a word presents the effect of being backward and of having a speech defect because in turn he gives orally what he heard instead of the correct speech pattern. "The speech sometimes becomes wholly unintelligible" and the qual-

DEAF EDUCATION OF THE

ity of voice undergoes great change. These pupils have increasingly progressive speech defects unless trained by a teacher who is well equipped to handle their special problems. Often the hard of hearing pupils experience academic failure and become behavior problems before they are placed in special classes. Some of these children have even been placed in classes for the mentally retarded before the true nature of the defect was recognized. Since the passage of the New York State Law in 1936, which requires the hearing of school children to be tested annually, these cases are growing fewer in number.

However, many children with a loss of fifty decibels can get along very well in a school with hearing children because of intellectual and personality endowments. On the other hand, less able pupils with a loss of forty decibels may have a history of retardation and behavior difficulties that require special treatment, and should be given an opportunity to make the necessary adjustments in a special school.

The Importance of Oral Instruction for the Deaf: It is extremely rare that anything is wrong with the speech organs of a deaf person. He is organically equipped to acquire speech and language. To deny him this right by teaching him through signs instead of by oral instruction, is to cut him off from his fellow-men.

How a Deaf Child Learns to Speak: On entering the kindergarten classes, the little ones, who are profoundly deaf, will produce inarticulate cries, grunts, and make known their wants with the use of gestures. A special program of education gives this child a vocabulary, teaches him to use his voice in speech patterns and gives him the language principles by which he can make himself understood. All this is a time consuming process and must be built up very carefully. The hearing child of five years of age speaks fluently, has a usable vocabulary, and understands language far beyond his ability in expression. These first five years in the hearing child's life are lost to the deaf child.

The deaf child coming to the kindergarten at the age of five has not one word in his vocabulary. His only means of communication has been by gestures. The kindergarten

teacher must first make him aware that when her lips move, something important happens. The teacher uses the tactile, visual, and auditory approaches by having the child feel the voice vibrations while he is watching her lips as she says a word. At one and the same time, she is teaching the lip-reading of this word, building up as rich a concept of meaning as possible, presenting the written word, and preparing the way for speech. By using a large mirror, and with the child's face next to hers, she gets him to imitate her speech formations. Then with the child holding one hand on her face and the other on his own, she starts the arduous task of teaching him to speak artificially. Of all pedagogical problems, teaching speech to the deaf is acknowledged the most difficult. The teaching of twenty-five words in speech in six months is rapid progress. Compare this with the hearing child of the same age who will have a thousand words or more in his vocabulary.

The speech of the deaf is labored, and naturally so, when consideration is given to the fact that they have been taught artificially to produce sounds and not just naturally to imitate what they hear as does the normal child. Every word in their vocabulary must be taught for the concept, pronunciation, and inflection. Mechanics, rhythm, pitch, accent, volume and quality of speech are conveyed to these pupils by visual, tactile, auditory and kinesthetic impressions as a substitute for the lost sense of hearing.

Language: Now that a start has been made in speech and lip-reading, it is necessary to teach language. The hearing child acquires his speech patterns and his speech simultaneously. Not so the deaf child. He may be able to lipread and to say the word "jump" but he cannot use it. Not until he is taught some pronouns and their meaning, can he use the word. Each language pattern, each idiom, each tense must be taught separately. Language is the most human activity and the greatest means of social intercourse. "The acquisition of a foreign language, under normal conditions of learning, is child's play compared to the difficult course that lies before the born deaf boy who has to acquire his mother-tongue artificially." The lack of speech and language cuts the deaf off from their fellow men. No effort is too great to bridge this gap.

DEAF EDUCATION OF THE

Group Hearing Aids: A group hearing aid is an electrical machine for amplifying speech. It has a pair of head phones for each pupil in the class and a rheostat that enables him to control the volume of sound. There is a microphone for the teacher. Some group hearing aids have individual microphones. The assistance received from the use of the hearing aid depends on the amount of residual hearing. Some pupils are enabled to hear music, some speech, others pitch and rhythm, still others hear only impulses. The results of training with a group hearing aid are:

1. Better speech development.
2. Improved interpretation of meanings as a result of better combined visual-auditory discrimination.
3. Aesthetic development through improved appreciation of the beauty of sound, whether the sound be speech or music.
4. Improved mental hygiene.

With hard of hearing pupils, a hearing aid is invaluable and through effective and co-ordinated programs for its continuous use there is more hope for the acoustically handicapped than ever before in the history of the world.

Special Schools: The type of provision that can be made for the special education of acoustically handicapped children is illustrated by Junior High School 47 in New York City which is supported by the Board of Education. It is the largest day school for the deaf in the United States. The school is equipped with a semi-soundproof room and audiometers for testing the hearing acuity of children in attendance and for those referred by other schools and outside agencies.

The school has the services of a nurse and of an otologist who gives examinations, makes diagnoses and assists with the guidance aspect of the clinical work.

The school has a special curriculum in Speech, Lip Reading, Language and Acoustic Training. (See SPEECH READING.) These are special tools the deaf child must acquire in order to function as a member in a continuously progressing society. The acquisition of these arts and skills makes for the actualization of the potentialities of each individual deaf child. In addition to this special work, the school covers the New York

City curriculum from kindergarten through the ninth year.

Because of the loss of hearing and its accompanying handicap in speech and the use of language, instruction of these pupils must be greatly individualized. Classes have ten children. The small class enables the teacher to be cognizant of each child's mental, physical, emotional, moral, vocational and avocational efficiency and to individualize guidance at all times.

The equipment in this school is different from that of other public schools. One complete side of each room is made up of windows, thereby giving the maximum amount of light so necessary when eyes must do the work of both sight and hearing. Lip-reading can thus be facilitated.

In addition to the unusual seating arrangement, the school is equipped with electrical group hearing aids. In some rooms each desk has a microphone for the child's use. In other rooms, there is just one microphone. All desks have earphones and individual controls for augmenting or decreasing the volume of sound transmitted. The use of hearing aids has proved to be of inestimable value to the children.

Free bus service from other parts of the city is provided by the Board of Education for the pupils of this school.

The school maintains an after school recreation room for the children, equipped with ping-pong tables, basket ball, skill ball, and similar games. A teacher of the school is always present to assist the children in their self-directed, self-planned activities.

Visual aids are of major importance in the specialized education of the deaf. A collection of the various types and devices unique to the teaching of the deaf have been gathered in Junior High School 47. A large collection of pictures, an important instructional tool of the deaf, miniature objects, slides, posters, movies and similar objective material is widely used.

A teacher's library of professional literature amounting to several hundred volumes offers assistance in this special field of education.

The Volta Bureau: The Volta Bureau located in Washington, D. C. was established in 1887 by Alexander Graham Bell for the increase and diffusion of knowledge relating

to the deaf. It has the largest library on deafness in the United States, the resources of which are at the disposal of research workers, teachers, and others interested in the deaf and the hard of hearing.

The *Volta Review* founded by Alexander Graham Bell in 1899 is the official organ of The American Association to Promote the Teaching of Speech to the Deaf. It is a monthly magazine for educators and parents of the deaf and for the hard of hearing. It contains professional articles for teachers and practical suggestions to parents of deaf children.

DEAN. The various types of deans include deans of boys and of girls in secondary schools, deans of men and of women in higher institutions, junior deans, academic or administrative deans of independent colleges and of the units or schools that comprise a university, graduate deans, and deans of administration on a university-wide basis.

Deans of girls and of women are engaged in both personnel services and administrative duties, including educational, vocational, and social guidance; administration of housing (for the college); and supervision of group activities; however, vocational guidance and full-time placement services are being increasingly performed by other persons. A similar service is performed by deans of boys and of men, whose duties usually are related to discipline and attendance, counseling, stu-

dent aid, housing (for the college), and health; to students in scholastic distress; and to the coordination of extracurricular life.

The position of junior dean has been established at Ohio State University in five colleges to advise freshmen and sophomores concerning courses, programs, vocations, and personal problems; to secure curricular and instructional improvements; and to stimulate the formation of student organizations with intellectual interests.

The dean of an independent college or of a unit within a university has general responsibility for college entrance, graduation, curriculum, instruction, staff, faculty meetings, student-faculty relations, budget, and equipment.

The graduate dean in a university coordinates the efforts of the various departments that offer work toward an advanced degree, especially the graduate programs in arts and sciences.

In some universities a dean of administration or dean of faculty acts as an administrative and supervisory assistant to the president, with duties similar to those performed by a vice-president.

DEBATING. Debating is one of the forms of oral argument conducted under rules. Formal debating as practiced in schools and colleges or universities is ordinarily undertaken by teams, one team presenting the arguments of the affirmative side of a proposition previously selected, the other the negative side. A team usually comprises three speakers (although sometimes two or occasionally one) each of whom delivers a main speech of ten or twelve minutes followed by a second speech, known as the rebuttal, of three or five minutes. Speakers of opposing teams alternate in presenting their speeches.

Debating is widely included as a curricular and an extracurricular activity in the secondary schools, colleges, and universities. In the secondary schools there may be an elective course in debating for upper class-

men offered by the Department of Speech or of English; or there may be debating societies advised or "coached" by an interested member of the faculty. In colleges and universities the curriculum generally contains courses of such titles as Principles of Argumentation and Debating, Forensics, Persuasion, or Debating, as well as an extracurricular activity in the same field. Thirty to fifty students, belonging to a debating society, compete for places on the varsity team, which may travel several hundred miles during the course of a semester to meet teams of other colleges in scheduled debates. Organizations such as the Mid-West Debate League, the Eastern Inter-Collegiate Debate League, the Western Conference Debate League, and Pi Kappa Delta, the intercollegiate honorary forensic fraternity, sponsor annual programs and tournaments and issue propositions of timely interest for the debaters. Some colleges and universities, through their Departments of Speech, hold debate contests for local secondary schools.

Although debating and disputation have been an important part of the classical tradition in education from the days of ancient Greece and Rome, in recent years some educators have questioned the ascribed values of formal debating. They feel that it does not provide participation for student bodies. Also, they question the values involved in the participant's assigned task of presenting one side of a proposition with the objective of winning a decision rather than arriving at an objective solution of the issues. To meet such criticisms other forms of debating have been developed: (a) *Decisionless debating* follows the classic form, but as the term implies does not entail the selection of a winning team. (b) In the so-called *Oregon Plan* each of the two speakers on a team is cross-examined for eight minutes by his opponent. Only specific questions are allowed by the chairman. The Oregon Plan may be used with or without decisions. (c) The *heckling* type of debate permits each speaker two minutes of uninterrupted discourse at the beginning and at the end of his presentation; in between, the audience is given the privilege of addressing questions to the speaker with the permission of the chairman. (d) The *direct-clash type* of debate is composed of an initial speech of five or eight minutes, given by the leader of each

side, in which the proposition is defined and analyzed. The negative indicates clearly his point of agreement and disagreement with the analysis of the affirmative. The remainder of the debate is then limited to the issues on which disagreement is clearly demonstrated. After each issue or phase of issue is presented there is a rebuttal, ending with a summary. The judges may rule that a "clash" or issue is ended when in their estimation one side has obtained a decided advantage. (e) Also popular are less formal types of debating such as *The British Type* and *The Congressional Type*. They follow broadly the parliamentary procedures of debate employed in the House of Commons and the United States Congress respectively. (f) In some schools formal debates have been replaced by the forum, the round table, and the panel discussion (*q.v.*). (g) The various forms of debate may also make use of the *audience ballot*, which is customarily phrased thus:

(Mark X in the proper place)

Before the debate I am

- _____ Favorable to the affirmative of the proposition
- _____ Neutral on the proposition
- _____ Opposed to the affirmative of the proposition

After the debate I am

- _____ Favorable to the affirmative of the proposition
- _____ Neutral on the proposition
- _____ Opposed to the affirmative of the proposition

Signed _____

Various methods of computing the audience ballot have been proposed to evaluate the success of the teams in the art of persuasion. (See SPEECH EDUCATION.) J.F.B.-1

DEGREES. College and university degrees are those designations which indicate the grade or rank to which one has been admitted because of his attainment, presumably scholarly. Each year about 165,000 persons in the United States receive the baccalaureate or first professional degree, 21,000 receive the master's or comparable degree, and 3,000, the doctorate.

The original baccalaureate (*q.v.*) degree, bachelor of arts (A.B.), has a continuous history of seven hundred years. It was first granted for the rank of apprenticed teacher; at this time three more years of work were required for the real university degree. In the fifteenth century it took four years to secure the A.B. at Oxford. After securing it one might study law, medicine, or theology.

From 1642 to 1851 there was no recognized liberal arts college in America which gave any other degree than the A.B. The bachelor of science (B.S.) was first conferred by Yale upon four graduates of its Sheffield Scientific School. The Bachelor of Philosophy was first set up by Brown University in 1850. *The doctorate* (Doctor of Philosophy—Ph.D.) was given first in 1861.

An incomplete list of the types of degrees granted in recent years by educational institutions includes the following:

Associate degrees	14
Bachelor's degrees	40
Master's degrees	34
Doctor's degrees	33
"Fellows"	20
"Graduates"	2
Licentiates	21
Designated (such as Civil Engineer)...	6
Special	6

The above list includes both honorary degrees and degrees given in course. The first honorary degree given in America was by Harvard in 1692. Few were given before 1776. In the academic year 1937-38, 1,500 honorary degrees were granted in the United States alone. Of these 571 were the degrees

of LL.D. (Doctor of Laws), 334 were D.D. (Doctor of Divinity), 142 were Litt.D. (Doctor of Literature or Letters), and 136 were Sc.D. (Doctor of Science). Among the other honorary degrees granted during that year were the degree of L.H.D. (Doctor of Humane Letters), A.M. (Master of Arts), Eng. D. (Doctor of Engineering), Mus.D. (Doctor of Music), Ped.D. (Doctor of Pedagogy), D.F.A. (Doctor of Fine Arts), M.S. (Master of Science), D.C.L. (Doctor of Classical Literature), Ed.D. (Doctor of Education), and S.P.D. (Doctor of Political Science). There were thirteen types of master's degrees, led by M.A. and M.S., and four types of baccalaureates. (See **GRADUATE EDUCATION**; **HIGHER EDUCATION**, **LIBERAL ARTS COLLEGE**; and such articles on professional education as **LEGAL EDUCATION** and **MEDICAL EDUCATION**.)

DELINQUENCY—See **JUVENILE DELINQUENTS**.

DELUSIONS. Delusions are false judgments or beliefs. Although they are not true to fact and are out of harmony with the individual's background and environment, they persist and do not seem irrational to him. Normal beliefs differ only in degree from those of the insane; and one can appear perfectly normal, yet believe in some absurd delusion.

These distortions of reality may arise from emotional conflict or may be induced temporarily through hypnosis. From the standpoint of content they are often classified as delusions of (1) melancholia, (2) persecution, and (3) grandeur. For example, the individual may feel very humble or he may think he has an incurable disease. The persecuted patient feels depressed and may hear voices accusing him of some fancied injustice, or he may interpret the well-intentioned remarks of his friends as reflections upon his integrity, intelligence, etc. He may even feel

that they are plotting or scheming against him. An individual may have delusions of an expansive nature, such as owning untold wealth or being the father of God. These, obviously, are examples of symptoms of abnormality, but the prejudices which we encounter in everyday life are illustrations of mild delusions.

Children, especially those who are more introverted, may develop the delusion that they are adopted or unwanted, because they have misinterpreted certain remarks and home situations; and all further experiences seem to confirm their beliefs.

The most satisfactory methods for preventing the development of delusions are: building up attitudes of self in harmony with the individual's abilities, creating opportunities for success, establishing feelings of security, and encouraging the individual to discuss his problems with a sympathetic adviser.

DEMENTIA—See MENTAL DEFICIENCY.

DEMOCRACY AND EDUCATION. It is a commonplace that every culture seeks to perpetuate itself. The familiar statement that the purpose of education is to "conserve the values of the past" is usually taken to mean that certain basic beliefs and values are to be transmitted to the younger generation. A culture, however, is a living, growing thing; it normally harbors a variety of conflicting values. Besides conserving the values of the past, therefore, it is necessary to select the values that are to be conserved. Decisions have to be made as to the true meaning of the culture, and these decisions become a basis for determining what should be taught and what may be taught.

Those values which are thus given preferred status are sometimes called the *frame of reference* for educational activities. This frame of reference may be determined by governmental authority, as in totalitarian countries, or by private agencies, as in parochial or other private schools, or by pressure

groups, with which we have become extensively familiar. Generally speaking, the purpose in each case is to protect certain particular beliefs and values by utilizing the schools as agencies for their perpetuation.

The practice of deciding in advance which beliefs and values are to be inculcated is sometimes designated as indoctrination or authoritarianism. At first glance it may easily appear that democracy cannot have a frame of reference of its own. It does not set up a recognized authority for deciding what the frame of reference is to be. It has no official creed by which to determine political or theological or economic orthodoxy. It is not antecedently committed to the preservation of any particular institution, or item of belief; it offers no advance assurance of protection for any kind of sacred and ultimate truth.

These negations result from the fact that democracy is concerned to protect the integrity of the individual against exploitation by social pressure. This protective attitude, however, is far from being just negative. It springs from a theory of values or "frame of reference" that is as positive and as distinctive as any other. From the standpoint of democracy our standards of conduct have their origin in the experiences of associated living; they cannot claim any transcendental or cosmic sanction. Democracy starts with the proposition that man becomes man by sharing in the larger life of a group. It is through participation in common purposes and common concerns that the individual achieves intellectual, social, and esthetic meanings and values. The democratic quality of a society is tested by the way in which it deals with the conflicts that inevitably arise. It is democratic to precisely the extent that it undertakes to resolve conflicts by widening the area of common concerns, that is, by enlarging the group through the discovery or creation of wider purposes so that the conflicting interests can unite on the basis of a common program. For this principle it claims universal applicability, ranging all the way from family life to industrial relations, and to international affairs. Democracy sets its own standard for right and wrong as a basis for a distinctive way of life.

This conception of democracy provides a perspective which reverses our traditional notion of education. Instead of identifying

DEMOCRACY AND EDUCATION

education with the process of fitting the individual to a predetermined social order, it makes education a process of adapting the social order so as to release the capacities of the individual. Education begins with the assimilation of the individual to his immediate group, which ordinarily is the family. It continues in all the other relations of life insofar as these lead to the sharing of purposes and interests, or the cultivation of the spirit of "team-work." All such education has a democratic quality to the extent that the individual has a voice in determining what the common purposes are to be, i.e., in adapting the "social order" to himself. Education becomes completely democratic when the ideal of continuously extending the domain of voluntary participation in joint undertakings becomes its test of progress or frame of reference.

Since common interests must emerge from an aggregate of individual interests, it would seem to follow that the latter can never be absorbed or replaced or even minimized by the former. The individual retains his everlasting uniqueness under all circumstances. The difference that democracy makes is that it provides a specific context or quality for individual living. In an ideal democracy every person would be concerned with extending the area of common concerns, not by giving up his particular interests and pursuits or by suppressing the particular interests of his neighbor, but by including them all in a comprehensive plan or scheme for the organization of social relationships. In other words, every person would live his life in his own way, within the limits set by the inclusive democratic purpose. This inclusive purpose would provide continuous intellectual, social, and esthetic stimulation to every member of the group and so make life a process of continuous education. The function of the schools in such a social order would presumably consist largely in imparting those skills and factual learnings which are not easily acquired on the job. Everything else in education would be an integral part of everyday living.

But we are not living in an ideal democracy. Our national culture has its source in a European, non-democratic civilization. We are living in a period of transition and confusion, which means that our schools have

a much larger and more difficult task. Their first and immediate task is so to organize their activities as to cultivate the spirit of cooperation and loyalty to the group in which democracy has its roots. That is, the schools must undertake to become within their own sphere, the best possible embodiment of democratic sentiment and practice in the management of their affairs. A further task is to widen the sense of group loyalty beyond the walls of the school to include the democratic activities that are going on in the community outside. And, lastly, the schools have the task of clarifying or intellectualizing the basic principle of democracy: that conflicts of a group with other groups, or conflicts within a group, are to be adjusted, wherever possible, not by taking our stand on eternal and immutable principles or values; but by discovering wider and more inclusive aims and purposes to which all can contribute as a common undertaking.

In brief, the task of the schools in a culture that professes allegiance to the ideal of democracy goes considerably beyond the obligation to conserve the values of the past. Both in school and out of school the ideals and practices of authoritarianism are carried over from earlier times, so that our values have become confused and contradictory. It follows, therefore, that the schools must assume responsibility both for the application or exemplification of democracy in their own procedures and for the interpretation of democracy as a distinctive way of life.

Progress in this direction must necessarily be slow, but much has already been accomplished. The changes that have resulted from the endeavors to subordinate curriculum requirements and administrative procedures to the needs of pupil development are extensive and significant. The gap between school and community is being bridged. Least progress has been made in the realization that democracy has an ethics of its own, which conflicts at vital points with traditional beliefs and practices. The realization that a choice of underlying philosophies is involved is still unclear, and it must be achieved if democratic education is to become completely conscious of what it is doing and if it is to enable the oncoming generation to assume intelligent direction of its affairs.

DEMOCRACY, PROBLEMS OF—See CITIZENSHIP, EDUCATION FOR.

DEMONSTRATION — See LECTURE DEMONSTRATION.

DEMONSTRATION TEACHING. Demonstration teaching usually refers to teaching situations that are planned and conducted especially for the benefit of prospective teachers who are undergoing their professional preparation. although demonstration teaching may also be used as a means of in-service education. The aim of demonstration teaching is to portray a variety of actual teaching situations which will give students a first-hand picture of the problems, methods, and procedures of teaching. It enables the students to observe closely how an experienced and capable teacher conducts a typical situation and then provides opportunity for the demonstration teacher, the students, and the college instructors to discuss the principles of good and bad teaching that underlie the procedures. It also enables students to observe the learning developments and difficulties and the personality problems of young pupils as they are handled by the demonstration teacher.

Several types of demonstration teaching may be referred to. A college class may go to a laboratory school or practice school to observe a demonstration of an actual and regular class situation, or the school teacher and pupils may go to the college classrooms to carry on the demonstration. A teacher or a student may conduct a class of the college students themselves in order to utilize the techniques of participant-observation and al-

low for discussion within the group of the teaching problems thus raised. In some cases demonstration teaching may even include the conduct of a class of pupils by one of the college students themselves.

Despite the advantages of demonstration teaching in the direction of a controlled situation which brings out clearly the principles of teaching deemed desirable and which portrays actual methods of good teaching, the limitation is that the controlled situation may not be a typical situation that prospective teachers may meet in their own jobs. Demonstration teaching also fails to give to the student himself the active participation necessary for full realization of the problems of teaching. Much can be gained from the observation of teaching, but full completion of the process requires responsible participation in actual teaching. (See STUDENT TEACHING; TEACHER EDUCATION.) R.F.B.

DENMARK, EDUCATION IN. The first schools in Denmark were established by the Christian missionaries in the ninth century. During the Middle Ages in the cathedral towns there were Latin schools, some very large with from 800 to 900 pupils, especially for the education of the clergy. When, after the reformation, the Lutheran church became the state church, schools were established in every town. The landed property formerly belonging to the Catholic church was confiscated by the state, but administered for the benefit of the church and the schools. There were no schools in the country parishes but instruction in the catechism was given by the parish clerk at least every Sunday and by the pastor regularly before the service. The bishop examined the children on his periodic visits.

This close connection between the established church and the schools has continued, especially in the country, until this day, and religious instruction has a prominent place in the curriculum of the schools.

The social reforms inaugurated in the eighteenth century benefited the peasants especially, who had been reduced to serfdom in part of the country. A school commission was appointed in 1789. Its program called for the establishment of a Christian and civil school, where the children were taught in conformity with the evangelical Christian doc-

DENMARK, EDUCATION IN

trine, and where such knowledge and proficiencies were imparted to them as to make them useful citizens. Education was made compulsory and normal schools for the education of teachers were established. The country schools belonging to the public domain had already been established in 1721 by the Danish King Frederik VI, and 240 good school buildings had been erected. About 1739, under Christian VI, there were schools in all parishes. The school law of July 29, 1814, consolidated what had already been done.

Many of the country schools were small and had only poor equipment. The teacher was also the clerk of the church and had a small farm in order to add to his meager salary. There was only one teacher and one classroom in every school, and the instruction was confined to religion and the three R's.

The present school system in Denmark has grown out of the past as a natural development and has followed the general trend in education in other democratic nations. Rural schools are now well housed and equipped, and in the larger communities there are several teachers to each school. In the cities the school buildings now compare very well with the standard established in the United States.

When a position for a teacher is vacant in a community the vacancy is published in the papers and candidates send their applications to the local school board. The school board and the parents' association together nominate candidates and their names are submitted to the school commission (*Skoledirektoratet*) for the county (*Amt*). In the cities the board of aldermen appoints the candidates, subject to the approval of the State Department of Education. Teachers enjoy tenure to the age of 65-70, and cannot be removed except on the most serious charges.

The school law of 1938 opened the way for consolidation of the smaller country schools into larger, centrally located schools with better equipment and more teachers. The teachers then became instructors in one subject through the grades, instead of being teachers who followed the class from year to year.

There is danger that consolidation of schools may result in the disappearance of the country school as a cultural center of the rural community. This would be deplored by many because the close connection between

the home and the school, and between the teacher and the community, is considered the most valuable asset in the Danish school system.

The compulsory school age is from 7 to 14 years. The city schools follow more or less the pattern in other countries. When a child has gone through the elementary school he enters the first year of the secondary school (the intermediate school) at the age of 11. The secondary school has a course of four years and ends with an examination, which entitles the pupil, if he passes the examination, to enter a one-year course that gives him a certificate (*Realeksamen*); or he can enter the *Gymnasium*, where he graduates after three years and obtains a certificate that entitles him to enter the university (*Studentereksamen*). The *Gymnasium* has three lines of study: classical languages, modern languages, and mathematical and natural science. The *Realeksamen* qualifies for civil service apprenticeship in the railways, postal service, telegraph, and customs services. These public services are all owned and operated by the government. Having passed an additional examination, the student with *Realeksamen* can enter the Royal Veterinary and Agricultural College, the College of Dentistry, or the High School of Commerce. Entrance to the university also qualifies for the State College of Engineering. This system of free education from the common school to the university, with equal opportunity for all, is the result of the reorganization of the whole school system by the school laws of 1903. Before that time it was expensive to attend the private Latin schools, and the cathedral schools prepared students for the university. Now most of the private secondary and high schools have been taken over by the state or the municipalities by the act of March 20, 1918.

In 1937-38 less than 10 per cent of the children attended private schools. There were 4,498 elementary schools with about half a million pupils and 17,150 teachers (10,175 men and 6,975 women). In Copenhagen, the capital, parents who are in the higher income brackets have to pay a small monthly sum for the education of their children. In 1937-38 the government expenditures on elementary schools was about 48 million *Kroner*, and that of the municipalities

60 million *Kroner* (the *Kroner* = \$2,680). Children who do not want to prepare for the professions generally leave the school at the age of 15 years. They are at that age confirmed in the church and begin to prepare themselves for their lifework. Many become apprentices and begin to work in a master mechanic's shop or in a business. They are apprenticed for 4 or 5 years and during that time have to attend evening classes in schools where they get theoretical instruction supplementary to their practical training. There are about 325 of these schools, with 35,000 students. The Technological Institute in Copenhagen, established in 1908, gives courses for artisans and manufacturers; courses for farmers are also given in the use of machinery. There is a department for each trade. About 8,000 students attended the institute in 1937.

The Folk Schools, secondary schools for adult education, have played an outstanding part in the development of modern Danish cooperative democracy. The idea for these schools was first developed by Bishop N. F. S. Grundtvig (1783-1872), who saw the need for a national and spiritual awakening of the Danish people through education during the tragic years of the Napoleonic wars. Christen Kold, the son of a poor shoemaker, was inspired by Grundtvig's writings, and in 1851, with Grundtvig's financial aid, he opened the first Danish Folk School "to teach young people to love God, their neighbors, and their country." It was a humble beginning—there were but fifteen students, all young men, who lived with Kold in an attic—but from this small beginning developed a movement that in 1937 comprised 58 schools with 5,700 students (2,800 men and 2,900 women).

The Folk Schools are subsidized by the government but are free of governmental control. They are not coeducational. There is a term of three months during the summer for women and one of five months during the winter for young men. The aim of these schools is to give the students a desire to work for the common good through cooperative effort. The schools were largely the cause of the spiritual and economic rebirth of Denmark after the disastrous war with Germany in 1864, after which they were established in great numbers. Their effect on

Danish life after World War II remains to be seen.

An attempt has been made to enlarge the principles of the Folk School and to apply them to the ideal of international cooperation in the International Folk School at Elsinore, founded in 1921 by Peter Manniche. Its object is to bring together men and women of many countries for the study of international relations, comparative culture, and languages.

There are two universities in Denmark. The larger and older is the University of Copenhagen, which was founded in 1479. The governing body is the *Constitutorium*, which consists of twenty professors elected by the faculty. The president, *Rector Magnificus*, is elected by the faculty for a period of two years. The administrator in charge of finances of the university is appointed by the Crown.

The students elect a student council, an advisory board in matters concerning the students. Instruction is open to all who have passed the entrance examination, and, except for a small registration fee, is free. The lectures are open to all. There are two terms: from September 1 to December 2, and from February 1 to June 7. The number of registered students is about 5,500, with 130 professors and instructors. The university has five faculties: theology, law and economics, medicine, arts, and science.

When the student considers himself ready he can present himself for the final examination for a degree. He is free to plan his course of study and to select the textbooks. Usually it takes from 5 to 7 years of study to qualify for the final examination. Those who pass their final examination with the grade *laudabilis* are entitled to submit a thesis to the faculty for the doctorate. If accepted, it has to be defended in public.

The university in Aarhus, Jylland, was founded in 1928 as an independent corporation and has about 1,000 students and 25 professors, with three faculties: medicine, law and economics, and philosophy and science.

The State College of Engineering in Copenhagen was founded in 1829, open to students with the entrance examination to the university. There is a small fee for the use of the laboratories. The college has four branches of study—chemical engineering, mechanical engineering, civil engineering, and electrical

engineering. The duration of the course is from 5 to 7 years.

The Veterinary School was established at the University of Copenhagen in 1773 and as the Royal Veterinary and Agricultural College in 1858. It has six departments: farming, veterinary and surgery, surveying, horticulture, forestry, and dairying. Other courses require the same qualifications as the university. The duration of study is from two and one-half years for the course in farming to five and one-half years for veterinary surgery. There are 21 agricultural schools, with 2,500 students and with courses lasting from 5 to 12 months.

The Commercial High School in Copenhagen has a two-year course and special evening courses for advanced study in commerce and trade. There are 120 other commercial schools throughout the country.

There are four state normal schools and 16 private normal schools for the education of teachers. Their graduates, after a four-year course, are qualified as teachers in the elementary and secondary schools. Teachers in the *Gymnasium* ordinarily must have a degree from the university. The Teachers High School in Copenhagen gives advanced courses to teachers. The government provides scholarships for advanced students at the university or in other countries.

Other educational establishments include the School of Dentistry, the Pharmaceutical College and the Royal Conservatory of Music, the Royal Academy of Fine Arts, and the Institute for Gymnastics and Schools for Navigation. Denmark offers many opportunities for postgraduate work, especially in the following schools: the Institute of Theoretical Physics and the Institute of Physiology, both endowed by the Rockefeller Foundation; the Finsen Institute for the study and cure of lupus and cancer of the skin; the Carlsberg Laboratories; the Institute of Biochemistry; the State Serum Institute; and many others. Information regarding these facilities for research work can be obtained from *Dansk Studie Oplysningskontor*, the University, Studiestraede 6, Copenhagen; *Anglo-Danish Students Bureau*, 98 Great Russell Street, London, W.C.1.; or the *American Scandinavian Foundation*, 116 East 64th Street, New York City.

The Royal Society of Arts and Sciences was

founded in 1742 to promote the historical, physiological, mathematical, and philosophical sciences by discussions and lectures, by the publication of scientific work and by the endowment of research. The society has two branches, one for history and philosophy with 30 resident members and with nonresident members not exceeding 60, and one for physical science and mathematics with 40 resident members and up to 80 nonresident members.

DENTAL CLINIC—See CLINIC, SCHOOL

DENTAL EDUCATION. The present system of dental education in the United States is the result of a long evolutionary process. As in medicine and law, the preceptorial or tutorial system was, until the 19th century, the method by which young men trained for dentistry. With the gradual development of the scientific foundation upon which dentistry rests, together with the accumulation of knowledge that could be reduced to an orderly form, it became apparent that a more comprehensive and more formal system was essential.

In 1840 the Baltimore College of Dental Surgery, acknowledged to be the first dental school in the world, was established, and as a privately owned institution set a pattern for the proprietary schools that sprang up later. In March, 1940, a centennial celebration was held at Baltimore. A volume of 1,061 pages records the addresses, scientific papers, and proceedings, which marked this important event in dental education.

In 1867, more than a quarter of a century after the first dental school, a new pattern was set which was destined to endure. Harvard University announced the establishment of a dental school closely integrated with its medical school. This action gave recognition to dentistry as a university discipline.

A significant fact today in the development of dental education is the complete disappearance of the proprietary dental school; all but four of the thirty-nine schools now in operation in the United States are integral parts of, or are affiliated with, universities.

Present Objectives of Dental Education. According to the report of the Curriculum Survey Committee of the American Association of Dental Schools, a study made possible by a grant from the Carnegie Corporation of New York, "... the program of undergraduate dental education should aim at training students in order that they may:

"(a) Be competent in the maintenance of oral health and the treatment of oral diseases, disorders, and deficiencies, with understanding and appreciation of the relationship between oral and systemic conditions in health and disease;

"(b) Cooperate effectively with persons engaged in allied fields of service;

"(c) Have interest in, and desire for, continuing professional study after graduation;

"(d) Practice dentistry with due regard for the social, economic and ethical relationship; and

"(e) Cooperate efficiently in community life."⁴

The Dental Course. The minimum educational requirement for admission to a dental school is the successful completion of two years of study in a liberal arts college. The college course must include a year's course in English, in biology, in physics, and in organic chemistry, and a half year's work in organic chemistry. Thirty-eight of the thirty-nine dental schools in the United States now follow these general requirements; the thirty-ninth requires three years of liberal arts work. Of the 1,784 graduates from the dental schools of the United States in June, 1942, 521—or 29 per cent—had a bachelor's or other degree before beginning dental study, and 174 were graduated from combined courses with both the bachelor's and the dental degrees; 74 had four years of college work; 350 had three years of training. In total, 61 per cent of these dental graduates had more than the minimum two years of work in liberal arts college. (These figures were compiled by the Council on Dental Education.)

In considering the problem of what type of man is best suited for dental training, mechanical ability all too often has received major emphasis. Students lacking in ability to master academic subjects often have been referred to dentistry with the belief that they would do better when working with concrete materials rather than with abstract concepts. The scope of abilities required today by the dentist is indicated by the opinion expressed in the Carnegie report: "Dentistry, represented by the great body of independent practitioners, must be intellectually vigorous, mechanically facile, esthetically felicitous, medically competent, ethically sincere, professionally keen, and socially altruistic."⁸

The normal professional course in dentistry covers four academic years. In a few schools the time may be shortened by individual students who elect to study in summer session or summer quarter. The curriculum is divided loosely into the preclinical or science courses and the clinical courses. The science courses include anatomy, physiology, chemistry, bacteriology, and pathology. Operative and prosthetic dentistry, orthodontia, and oral surgery are the major clinical courses.

For many years graduate courses for dentists have been available, especially in basic science fields, but enrollment has always been small. In the year 1939-40 only 126 students were working for a degree.⁵ One of the chief reasons for this is that many dental graduates who wish to work for another degree prefer the degree in medicine. In 1937-38, 45 graduate degrees were awarded, distributed as follows:

Master of Science in Prosthesis.....	1
Master of Dental Surgery.....	4
Master of Dental Science.....	21
Master of Dental Science in Orthodontics..	5
Master of Science.....	13
Master of Public Health.....	1

Postgraduate courses in dentistry vary widely in length and breadth. For graduates who wish to prepare for specialization, courses extending throughout one or two years are available. These courses are offered chiefly in the fields of orthodontia, prosthodontia, and oral surgery. Three schools offer courses in public health dentistry, aimed at preparing dental graduates for positions as directors of dental health in city or state departments of health. Upon completion of

DENTAL EDUCATION

these courses, certificates of proficiency are awarded. Short courses, the so-called refresher courses, are offered by the various dental schools, by dental societies, and by commercial interests.

Thirty-five dental schools confer the degree of Doctor of Dental Surgery (D.D.S.) upon candidates who successfully complete the professional course. Four schools confer the degree of Doctor of Dental Medicine (D.M.D.). The dental profession and state dental examining and licensing boards recognize no distinction in inherent values as between the two degrees.

Organizations Related to Dental Education. The *Council on Dental Education of the American Dental Association* consists of nine members—three representatives each of the American Dental Association, the American Association of Dental Schools, and the National Association of Dental Examiners. Its duties are to study conditions of dental education and to suggest to the American Dental Association methods by which these conditions may be improved. It is also the accrediting agency for dental education, and it is at present engaged in inspecting the dental schools of the United States for the purpose of rating them.

The thirty-nine schools of the United States and four schools in Canada are members of the *American Association of Dental Schools*. The purpose of this organization is to improve dental education in all its phases. The *Journal of Dental Education* is the official journal of the Association. The *Proceedings* of the annual session are published annually.

The *National Association of Dental Examiners* is a voluntary association of the members of the forty-nine state boards of dental examiners. Its purpose, broadly, is to raise the standard of methods of examining candidates for license to practice. It has no legal status.

The *National Board of Dental Examiners* is organized as a part of the American Dental Association. It conducts examinations in all parts of the country in the basic sciences and in the theoretical aspects of the clinical courses. It has no legal status but it issues to successful candidates a certificate of qualification which twelve state boards are permitted to recognize.

Licensure. Before a graduate of a recognized or approved dental school may practice his profession he must satisfy the legal requirements of the state by passing an examination to determine his fitness to practice. In some states the *state board of dental examiners* set up their own requirements for an approved dental school, and thereby become an accrediting agency.

Trends. "It is evident that dental education is entering a new cycle—one which is characterized by greater university interest and control, by expansion of research activities, and by intensification of interest in the public health aspects of dentistry."⁵ The rapid social changes now taking place are bound to involve the procedures of dental education. Harvard University has already started an experiment in expanding the requirements in medicine so that the M.D. as well as the D.M.D. degree will be awarded successful candidates. Another university, by making its entrance requirements and its first two years identical with that of medical school has made it possible for the dental graduate to earn a medical degree in an additional two years. The medical graduate also can earn a dental degree in two additional years.

From these developments "is emerging a step which is entirely logical and which should not be too difficult to realize. This step is the closer coordination of dental and medical education. To accomplish this satisfactorily will require that the barnacles of traditional prejudice be scraped off both dentistry and medicine, and that the problem be approached with a truly scientific attitude by both groups. Considerations of public welfare demand that this forward step be made."⁵ (See also MEDICAL EDUCATION.) L.M.S.M.

DEPARTMENT MEETING — See **TEACHERS' MEETING.**

DEPARTMENT OF EDUCATION— See **UNITED STATES OFFICE OF EDUCATION.**

DEPARTMENTALIZATION. In order to secure greater specialization of teaching, many schools have been organized on a departmental basis. Many elementary schools have this type of organization in the intermediate grades, and a few schools departmentalize all of the grades. In a large departmentalized school, for example, one teacher may teach a single subject, such as arithmetic, to all of the pupils of the intermediate grades. In a small school the teacher may teach all of the pupils of the entire elementary school. In smaller schools which use departmentalization only in the upper grades, it is usually found that the same teacher is teaching two or three subjects each day to fourth, fifth and sixth grade pupils, or to seventh and eighth grade pupils. Departmentalization is the common practice in junior and senior high schools.

Commonly, the teacher in the departmentalized type of organization has a single room assigned to her which may be specially equipped to facilitate the teaching of her subject. The pupils in this type of school commonly move from room to room to receive instruction in the different subjects included in the curriculum.

Specialization in teaching has gained favor in elementary school organization during the past twenty years. The theoretical arguments both pro and con have been postulated by many writers. Those who argue on the basis of administrative feasibility favor departmentalization. Those who argue for the welfare of children versus the worshiping of subject matter are often opposed to departmentalization.

The principal argument for the departmental organization is that it brings the services of more competent persons to the school program and assures a more sequential and better ordered curriculum. The principal objections center in the type of curriculum which is fostered and the division of the child's program into many parts. The plan obviously assumes a subject curriculum in which the principal qualification for teaching is competence in the subject. This is held by many to be an inadequate and distorted view of the

function of teaching elementary school children. The plan is condemned because it divides the child's day into many small parts, not giving long, intimate contacts and close association with a single teacher.

The trend during the past decade has been away from departmentalization in the elementary schools. In the secondary schools it is still the prevailing system of organization. Such new curricular movements as the core-curriculum, integration, broad-fields curriculum (*q.q.v.*) etc. attempt to modify traditional narrow subject matter boundaries, without sacrificing the needed specialization of the secondary school teacher. O.G.J.

DEPENDENT CHILDREN. In a broad sense the term "dependent" may be applied to any child whose parents do not care for him properly, and who, therefore, must look to society for support. Legally, a distinction usually is made between *dependent* children, whose parents *cannot* provide for them; and *neglected* children, whose parents *will not* do so. Thus, in some states, the transfer of a dependent child to a foster home is accomplished without the intervention of the Juvenile Court; whereas, a neglected child, under similar circumstances, would be brought before the court on the assumption that he is a potential delinquent. From the standpoint of child welfare, however, this distinction is somewhat artificial, since both types of children are dependent.

Causes of child dependency include illness, death, unemployment, or low earning power of either or both parents; homes broken by death, divorce, or desertion; and parental indifference toward, or rejection of the child (See **REJECTED CHILD**). War is also a major cause, and one of the chief activities of the American Legion is to care for the dependent children of veterans.

The most common approach to this problem in the past was to place dependent children in private or public institutions, and to prosecute wilfully neglectful or cruel parents. The more recent trend (based upon an application of psychology and psychiatry) is to consider the problem as one of social case work. It is recognized that a child's needs do not end with the furnishing of food, clothing, and shelter, but that, to develop normally, he must also have affection and emotional security. There is no adequate substitute for

the home in meeting this latter need; and, therefore, the present tendency in dealing with dependent children is to keep the family intact, if possible. This may be accomplished partly by benefits from Workmen's Compensation laws or by direct aid to mothers (mothers' pensions) which are now available in practically all states through the cooperation of the Federal Government under the Social Security Act of 1935. Some states still debar unmarried mothers from the benefit of such aid, but the Social Security Act makes no distinction in this matter. A desirable feature of mothers' pensions is that they not only allow dependent children to remain at home, but they also preclude the necessity for mothers to obtain gainful employment, thus being forced to neglect their offspring. Where the pension is insufficient to support the family, and the mother must work, day nurseries where small children can be properly cared for have been organized. If, despite these aids, the family cannot be kept together, the foster home is regarded as the next best solution. In homes where the child is unwanted, or where the alcoholism, immorality, or irresponsibility of parents are such as to be detrimental to his interests, placement in foster homes or institutions may be recommended. Foster homes are now generally preferred, but institutions occasionally may be more suitable if the dependency is to be temporary and it is undesirable for the child to become attached to another family. The majority of dependent and neglected children are still cared for in institutions, although these are coming to be regarded as a last resort. Despite their drawbacks they are valuable as centers for observation and research; are helpful in cases where medical treatment is required, and where it is undesirable to separate children of a large family. No one method of caring for dependent children will meet adequately all the needs in this field.

DEPOSITORY FOR SCHOOL FUNDS

—See FINANCE, SCHOOL.

DEPRECIATION. Depreciation means loss in service value, owing to wear and tear of usage, physical decay, or obsolescence.

The rate of depreciation of a school building varies with the type of structure and the care and maintenance provided; it is computed by the following formula:

$$d = \frac{V_o - V_s}{n}$$

In this formula, d = annual depreciation, V_o = original cost of the building, V_s = the salvage value, and n = the life of the building in years.

A depreciation reserve is established by setting aside annually from income an amount equal to the estimated depreciation. This amount will be sufficient to replace the building at the end of its period of usefulness. Experience has taught authorities that it is sometimes difficult to protect such sinking funds against misuse, mismanagement, or loss; therefore many authorities in school finance recommend the replacement of school buildings through the issuance of bonds, if replacement cannot be met out of current revenue. DETERMINISM IN EDUCATION. The theory that mental abilities are purely innate and neither increased nor diminished by environmental influences may properly be designated as "psychological determinism." The application of this theory to the problem of changing human behavior, which is the basic problem of education, is analogous to such other applications of the deterministic hypothesis as the explanation of social, and

especially political, changes in terms solely of "economic determinism."

The influence of psychological determinism upon educational theory and practice has been particularly marked since the concept of "general intelligence" gained wide acceptance with the development of the so-called intelligence tests during the second decade of the 20th century, and especially since the convenient concept of the "intelligence quotient" was introduced to designate the relation between "mental age" and "chronological age." Since repeated tests seemed to indicate, for any one individual or any one group, a certain degree of constancy, the hypothesis that mentality was determined in a substantial measure by physical heredity was greatly strengthened, and since some exceptions to the rule of constancy could be satisfactorily explained by hypothesizing either faulty tests or variations or errors, in the application and scoring of the tests, there was a clear tendency among psychologists toward the conclusion that physical heredity was, for all practical purposes, the only determining factor.

This was undoubtedly the attitude of most American psychologists, including educational psychologists, in 1921, when the publication of the results of the intelligence tests as applied to drafted soldiers in the Army camps in 1917-18 aroused wide public interest in the question of heredity *vs.* environment in the determination of mental traits. The organization and interpretation of the mass of data collected in this, the most extensive testing program up to that time, were clearly governed by the hereditarian hypothesis. The differences disclosed, for example, among soldiers from different sections of the country were ascribed solely to differences in the genes, with the correlative inference that differences in environmental or cultural stimulus and opportunity had nothing to do with them. The natural result was a wave of skepticism regarding the possibilities of effecting fundamental changes in human beings through the processes of education. By the same token, the whole theory of political democracy came into question.

Only a very few persons trained in psychology ventured to question the basic assumptions that were involved in the fatalistic conclusions drawn from the evidence. While these nonconformists were practically os-

tracized from the psychological camp, their contentions and criticisms were sufficiently cogent to impel the National Society for the Study of Education to promote and sponsor a series of careful investigations on the relative influence of nature and nurture in the development of general intelligence. Other investigations, both in the United States and in Great Britain, were also undertaken, and in 1928 the Society published its 27th *Yearbook* reporting the studies carried on under its sponsorship and summarizing all other pertinent studies that had been reported up to that time.

The net result of these activities was both a definite clarification of the issue and the assembling of evidence clearly invalidating the assumption that general intelligence as reflected in the IQ is entirely unaffected by cultural or environmental influences, although a modified hypothesis to the effect that heredity plays the major role seemed to be just as clearly justified. The important outcome, however, was that the backbone of extreme determinism in education was broken. While educational and other environmental influences might operate within limits, it was demonstrated that their contribution, under the proper conditions, could be made both significant and substantial.

The investigations were continued during the following decade, with important improvements in techniques of testing and important refinements in the interpretation of results. In 1938, the Society published its second *Yearbook* (the 37th of the Society's series) on the nature-nurture controversy. In general, the conclusions drawn ten years previously were confirmed, with certainly a slight, and, in the opinion of some psychologists, a very considerable increase of evidence in favor of the theory of IQ plasticity, especially during the early childhood years.

At the present writing (1943) the extreme theory of determinism in education, characteristic of the thinking of the early 1920's, is no longer an issue. In part because of the conflicting ideologies that brought about World War II, the dominant interest in the United States shifted to educational measures aimed to correct the injustices, and more, the inhumanities, that have resulted from the use of the concept of psychological determinism as a fallacious justification of racial intol-

erance, racial inequities, and racial persecution. For whatever the influence of physical heredity may be in determining mental differences among individuals of the same race, the investigations so far reported fail signally to justify the assumption that there are irremediable native differences in mentality among the medians of racial groups. DEWEY, JOHN (1859-1952). John Dewey has been the most significant influence in the philosophy of education in America for almost fifty years. In 1896, two years after he assumed the post as head of the department of philosophy at the University of Chicago, he founded the University of Chicago Elementary School. Thus was expressed his faith in the necessary union of philosophy and education, which has been the inspiration of his work ever since. In the little brochure called "My Pedagogic Creed" (1897), he states that "education thus conceived marks the most perfect and intimate union of science and art conceivable in human experience."

His thought-system has most often been classified as experimentalism, but as in the case of many other penetrating thinkers—John Locke comes to mind—categorizing and labeling in the case of Dewey are dangerous conveniences. His has been a total view of man, society, and nature. In the reconstruction

of experience Dewey finds the unifying concept bridging the gap between art and science, theory and practice, education and philosophy.

In a great many books, articles, and addresses, spanning the years from 1896 (*Interest as Related to Will*) to 1938 (*Experience and Education*), Dewey has expounded his philosophy of education, stressing the meaning of education, the meaning of the school, of the curriculum, and of method.

Meaning of Education. He has sought to resolve some of the most perplexing inconsistencies and contradictions as to the meaning of education, its purpose and goal, its means and end. He holds that education is a process of living and not some kind of preparation for future living. In education, the process and the goal are one and the same; namely, the continuing reconstruction of experience in such a way as to add to the meaning of experience and give increased control over the process. This concept of reconstruction aiming at further reconstruction and at nothing fixed or definable has troubled many students of Dewey's educational philosophy. It seems vulnerable to the same refutation that he himself has adduced against the statement of the goal of education in terms of the harmonious development of all the powers and capacities; development toward what? However, Dewey's concept of democracy lends meaning to what would otherwise be a disturbing Heraclitean enigma. Greater democracy, in the sense of more intelligent sharing by each member of every group in the activities and interests of the group and greater sharing of all groups in the activities and interests of other groups—this is the ultimate goal which gives an otherwise lacking direction to the reconstruction of experience which is both process and proximate goal of education. The Industrial Revolution, with its concomitant social results, has convinced him of the need to stress cooperative (shared) living as a counterpoise to stark individualism.

Another contradiction with which Dewey's philosophy has concerned itself arises out of the two sides of the educational process, the psychological and the sociological. In educational thinking, these two sides have been conceived as antithetic, and various compromises have been advocated; e.g., education

should strive for the maximum of individual liberty consistent with social stability. Dewey's teaching here is that neither the psychological side nor the sociological side should be subordinated to the other, nor is compromise the solution. Granted a democratic society, the only possible adjustment is that which arises from putting the individual in complete possession of his powers. But these powers have meaning only as the individual is conceived as active in social relationships. Therefore, education must begin with the individual's capacities, powers, habits; but these must be interpreted in terms of their social equivalents. Thus Dewey reveals the weakness in all purely psychological definitions of education,—they stress development with no reference to the use to which the developed powers are to be put. But he also reveals the weakness in all purely sociological definitions of education,—they lead to a forced and external process of squeezing the individual into a preconceived social pattern. Neither meets the test of democratic education.

Meaning of the School. Dewey rejects the superficial idea that the school is a convenience for caring for children while they are growing up, or that it is a place where certain facts are to be learned. On the contrary, it is a form of community life, a process of living, where, to be sure, the complexities of social life must be simplified, purified, and balanced. The early school experiences, in order to secure continuity, must grow out of home experiences, for these have been among the most meaningful activities of the race. This implied parallelism between racial and individual development is a recurrent note in Dewey's writings, and has perhaps contributed with the more explicit formulations of other writers to keep the recapitulation theory alive.

The school must provide activities in which relations with others are prominent, for social and moral living come close to being synonymous with Dewey. In the same spirit, and for the same reason, the teacher must be a member of the school community, rather than an official appointed to impose certain ideas. The discipline of the school should be a community enterprise. In some of his writings, Dewey has brought this basic gospel of shared living to bear on some of the knotty

problems of school administration, academic freedom, relation of the public to the schools, and similar matters.

Curriculum and Method. The curriculum should be a gradual differentiation out of the funded capital of civilization and not a schematization of logically organized subjects, as with William T. Harris (*q.v.*). Dewey takes notice of the Herbartian doctrine of concentration (See HERBART), but only to reject it as "radiation." The organizing principle of the curriculum should be the social life of the child at his particular stage of development, with expressive or constructive activities at the center, because here he is "at work along the same general constructive lines as those which have brought civilization into being." This teaching is perhaps the most clearly recognizable influence of Dewey's philosophy on the contemporaneous progressive education movement (*q.v.*).

In method, the active side should precede the passive. Dewey's epistemology holds consciousness to be essentially motor, and knowledge to be a by-product of action. Even the emotions are the reflex of action and mental health can be stimulated only when emotions are exercised in corresponding activities. Some of Dewey's great predecessors, notably Froebel (*q.v.*), had stressed the indispensable nature of activities in all true learning.

Among the many other contributions of Dewey to the understanding of education, two should be briefly mentioned.

The first was his reconciliation of the two supposedly opposed doctrines of interest and effort. This reconciliation consisted in his showing that genuine *effort* can be invited only by connecting an activity with some end with which the learner has identified himself—some end in which he has an *interest*. Thus he dismissed the dichotomy between the schools of hard and soft pedagogy, and clarified the true meaning of motivation.

The second was his well-known analysis of effective thinking. This called attention to the importance of the problem in stimulating thinking, and of the need to locate and define the heart of the difficulty, to examine suggestions and possible solutions, to develop the bearings of each and to submit the most probable solution to the test of action or experimentation. This analysis supplied powerful impetus to the so-called problem method

of teaching, and to its derivative, the project method (*qq.v.*). P.R.V.C.

DEXTRALITY—See **HANDEDNESS**.

DIAGNOSIS, EDUCATIONAL. Educational diagnosis is the "procedure of determining the nature and causes of basic and general learning difficulties." While teachers have always been concerned with the attempt to discover and to correct the conditions which interfere with efficient learning, the teacher today can utilize a better understanding of the psychology of learning and a wider array of diagnostic procedures than were available to the teachers of even a generation ago.

The problem of discovering why one child has not learned to read or why another cannot multiply one fraction by another is sometimes so simple that the teacher may find the causes quickly; or it may be so complex as to baffle the clinician despite his utilization of ingenious testing devices.

Once it has been determined that the pupil is experiencing difficulty in learning, the teacher can begin search for the cause. As a necessary first step the teacher must find out whether this is an isolated difficulty or part of a more general problem. Is the pupil deficient in all subjects or only in arithmetic? Is he deficient in all phases of arithmetic or only in work with fractions? Is he deficient in all examples with fractions or only those involving the multiplication of fractions? etc. The more specific the teacher can be in describing the child's learning difficulty the greater is the likelihood of the teacher's being able to find the causes and to plan the program of remedial instruction.

A diagnostic test is one which is administered in order to discover the weaknesses or strengths of pupils in a specified portion of a particular subject or area of learning. Diagnostic tests, in general, cover a restricted section of a subject, e.g., capitalization or punctuation in English, but cover it thoroughly enough to reveal any errors that may possibly be made. A general achievement test may cover a whole subject, as American history, but only a few items can be included because the area is so large; on the other hand, a diagnostic test covers thoroughly a certain phase of American history. Since the purpose of a diagnostic test is to discover degrees of proficiency, no wide sweep of material is possible because many portions may be missed. One investigation found that more than a hundred chances for making errors were presented in working simple problems and exercises dealing with decimals; clearly, any diagnostic test that purports to measure the exact nature of the errors which the child makes when working with decimals must be limited in scope to exercises and problems of this sort and must ignore other types of arithmetic work. In other instances, the diagnostic test need not be so detailed since all that the teacher may need to know is the type of error made by the students. How fine the diagnosis should be depends, therefore, on the use that will be made of the test results.

The common method of devising a diagnostic test is to present a number of written exercises and then have pupils make the responses demanded. For diagnosing errors in punctuation, the teacher can ask the child to supply the correct punctuation in a series of printed or mimeographed sentences which involve various uses of the comma, quotation marks, semicolon, etc. After the exercises have been corrected and the mistakes tabulated, the number of errors and the kinds of mistakes made by the various pupils are revealed. Tests involving written responses deal chiefly with tool subjects and the mechanical aspects of subjects. There are several published diagnostic tests, especially in English and mathematics.

Another method of diagnostic testing involves performance of some kind which is usually more complicated than punctuation or the solution of mechanical problems. In

this instance, as the response may be given orally, the teachers must detect errors by observation. A good example of performance is that in which a pupil reads a selection orally and the teacher observes closely to detect the quality of the reading, including such factors as pauses, word calling, expression, and pronunciation. Methods for observing eye movements during reading belong under this performance technique. Having the student write a composition is a valuable aid to diagnosis in an English class because he is under no examination pressure and his errors are probably the ones he makes under normal conditions. In solving a problem or arriving at a conclusion, pupils are called upon to trace orally the steps taken; here again the teacher observes and diagnoses. Similar situations are found in singing, playing instruments, handling machines, speaking in public, and participating in sports requiring skilled performances.

In a sense, every response a pupil makes affords the teacher an opportunity to diagnose; the quiz, the hour examination, daily recitation, reports, notebooks, public speeches, and conferences are all response situations which show the shortcomings of instruction or the deficiencies in learning. Every teacher can and should use these informal kinds of tests to assist in continuous diagnosis.

Diagnostic tests reveal errors; they do not show the causes of these mistakes. Behind the errors may be carelessness, poor reading ability, lack of knowledge, low mental capacity, wrong interpretations, and similar psychological and educational shortcomings. It is therefore usually inadequate to base educational diagnosis and to plan remedial work solely upon the results of a diagnostic test. Where the pupil's mental ability may be responsible for his difficulties, an examination of his scores on intelligence tests may be helpful. A physical examination may reveal such physical defects as poor vision or poor hearing. An analysis of the child's work habits may indicate both the nature and the source of his learning difficulties. At times the pupil's personality difficulties may lead to a degree of emotional maladjustment which interferes with all school learning, or it may result in dislike for only a particular subject or teacher.

Although the modern teacher is well pre-

pared to discover and to deal with many instances of learning difficulties, he usually does not have the time, the facilities, or the training needed for the examination and treatment of complex cases in which the causes are hard to find and to treat. These are the children who are referred usually to such agencies as psychological clinics, educational clinics, guidance centers, personnel bureaus, and child guidance clinics. At such an agency the youngster is studied by psychologists, psychiatrists, social workers, and physicians. Some clinics are equipped to undertake the remedial program that is needed, while others merely plan the program and advise the teachers who put it into effect.

DIAGNOSTIC TEST—See DIAGNOSIS, EDUCATIONAL.

DIALECTIC METHOD—See SOCRATIC METHOD.

DIALECTICAL PSYCHOLOGY — See PSYCHOLOGY, SCHOOLS OF.

DIARY, CLASS. Many teachers in elementary schools keep a detailed account of the educational activities in which their pupils engage during a school term. Such an account, usually referred to as a class diary, makes it possible for the reader to gain a reasonably correct impression of the scope and sequence of the activities engaged in and of the pupils' growth in skills, habits, concepts, and appreciations.

The class diary, though used in both the traditional school and the child-centered school, is not only used more frequently but also serves a more specific need in those schools that do not adhere strictly to formal courses of study.

In the traditional school, it is customary for teachers to be expected to adhere closely to a prescribed course of study. After consulting the syllabi, teachers indicate in a plan book the material to be taught during the several periods of the day. At the end of each day, any deviations from the stated plan are indicated in the plan book. To assure a

policy of strict adherence to the prescribed courses of study, the teachers are required each week to submit their daily plans for the following week to the principal or supervisor for approval. In this way, the school administrator is certain that the pupils are being provided the experiences prescribed for each grade.

Recently, not only in the child-centered schools but also in schools of the traditional type, both teachers and pupils have been given more freedom to choose the activities in which they will engage during the term. Syllabi, when used, serve as guides and not as prescriptions. Teachers are encouraged to experiment with both methods and curriculum materials in order to provide a program which will come closer to meeting the individual needs and interests of their pupils. In the absence of prescribed syllabi, a teacher who exercises her freedom in the selection of activities to be engaged in by her pupils must also be ready to defend her classroom program at all times, since she is held strictly accountable for the educational growth of her pupils. The class diary probably is the teacher's best single source of tangible evidence in support of her program.

In some schools teachers are encouraged, and in many instances required, to keep class diaries for the use of other teachers who may wish to use them as a source of additional knowledge of materials and methods of instruction. It is not uncommon for teachers with little or no experience in teaching and without the guidance of prescribed syllabi to be required to keep class diaries for the purpose of evaluating their work at the end of the term. Frequently, the class diary is filed in the school library or principal's office to be used by teachers of the same group during later terms as a help in gaining a better understanding of the educational experiences in which their pupils have engaged previously. As a means of interpreting the philosophy and work of the school to the public, the class diary is invaluable. (See PUBLIC RELATIONS, SCHOOL.)

Since it is impossible to record all classroom happenings and their results, the contents of a specific diary record in final form are usually selected in terms of the main purposes for which they are intended.

No matter for whom the diary is intended, the narrative account giving the step-by-step

progress of the class in meeting the goals of the school program is helpful in providing a basis for an understanding of the work of the class. The narrative account may contain daily entries of the activities of the class or it may be simply a summary of the activities as they developed. A descriptive account of the units of work, projects, or problems studied during the term is particularly helpful to the reader, no matter what may be his purpose. In addition to showing the step-by-step progress in these activities, the teacher's evaluation of the experiences is valuable, especially to teachers who read the report to increase their knowledge of methods and materials of instruction.

The class diary in final form, as it is presented to the reader, may contain a variety of materials in addition to the narrative account of the classroom activities. Samples of the pupils' work, such as original stories and poems, drawings and paintings, and arithmetic and other subject-matter papers, may be included as evidence of the quality of work done by the group, or they may be used to illustrate points referred to in the narrative account. Lists of books read by the pupils show the extent and quality of their reading. Photographs of pupils at work on various activities can be used to illustrate methods of work in the classroom or points emphasized in the narrative account.

Although trips or excursions taken by the class naturally are mentioned in the narrative account, some teachers prefer to treat these separately for the purpose of emphasis. While it does not seem necessary to include the day's schedule of activities for each day of the term covered in the diary, samples of a typical day's work, as well as the schedule of an atypical day, are sometimes helpful in giving an accurate picture of the work of the class. Some teachers include in the final form of their diaries a list of the concepts, skills, habits, and appreciations developed during the term. Frequently, samples of tests are included to show one of the methods used by the teachers in evaluating the growth of her children. As evidence of growth in habits and appreciation, the responses or actions of the children, as observed by the teachers, are sometimes described in detail.

The entries concerning day-by-day activities may be made by the teacher, may be made by the class but written by the teacher, or,

in one of the higher grades, may be made by a pupil. The daily entries usually include a schedule of the day's work. This may or may not be accompanied by a summary of plans made or the work accomplished each day on the unit of work in progress. The regular daily entries or notations are characteristic of this type of diary, which make it somewhat similar to the log kept on board a ship. It is probably for this reason that such a record is sometimes referred to as the class log.

DIFFERENCE, STATISTICAL — See SIGNIFICANT DIFFERENCE.

DIFFERENTIATED ASSIGNMENT— See ASSIGNMENTS.

DIFFICULTY OF TEST ELEMENTS. The scores obtained by a group of pupils on a given test depend not only upon the ability of the group, but also upon the difficulty of the items included on the test. It is, therefore, important that the difficulty of test items be controlled in order to secure the best possible measure of achievement. In general, test items should be selected for difficulty in such a way that the average score obtained on the test is approximately one-half of the possible score. This does not mean, however, that each item should be failed by fifty per cent of the group, thus placing each item at the same level of difficulty. When a test is constructed with a view to its being used in several grades, for example, a standardized achievement test in arithmetic which is intended for grades III to VIII, it is clearly impossible to have the average score of fifty per cent at each grade level on which the test is used.

It is also necessary to think in terms of the use to which the test results are to be put. The usual instructional test should represent the level of difficulty which the teacher thinks it desirable for the class to achieve. The teacher-made test may well set a standard of 100 per cent as the goal to be reached by the student; in such a test the difficulty value of the items must necessarily make it possible, statistically, for the students to reach the goal. If the test is being used to select pupils of superior attainment in order to award schol-

astic honors, test items should have a very high level of difficulty, in order to discriminate more adequately among the superior pupils at the upper end of the scale. If the test is being used to isolate pupils of very poor attainment, items of low difficulty should be included in order to measure the performance of the poorer students with greater accuracy. When tests are being used for diagnostic purposes, the level of difficulty of the items included is of only secondary importance. More urgent is the necessity of testing all relevant skills and knowledge, regardless of the level of difficulty of the items used.

A difficulty scale is one in which the items comprising the scale are arranged in order from easiest to hardest. The level of difficulty, or difficulty score, of an item is ordinarily obtained by determining the percentage of individuals who solve the problem or who answer the question correctly. A person's score on such a scale may be computed by taking either the most difficult problem solved or the total number of correct responses. J.J.

DIOCESAN HIGH SCHOOL—See ROMAN CATHOLIC EDUCATION.

DIOCESAN SUPERINTENDENT OF SCHOOLS. The diocesan superintendent of Catholic schools is the executive officer of the bishop and the diocesan board of education. He represents diocesan leadership in Catholic educational endeavor and in relations with public authorities. His chief task is to establish high standards within the school system of the diocese without in any way encroaching on the prerogatives of pastors or religious superiors. His duties are quite similar to those of a state superintendent of public instruction, but he does not enjoy the same degree of power in enforcing regulations, since many bishops do not delegate full authority to the diocesan superintendent. In 1942, of the 112 dioceses in the country, 95 listed a diocesan superintendent of schools. (See ROMAN CATHOLIC EDUCATION.) F.M.C.

DIPHTHERIA—See COMMUNICABLE DISEASES OF CHILDHOOD.

DIRECT METHOD (in Character Education)—See CHARACTER EDUCATION.

DIRECT METHOD OF TEACHING FOREIGN LANGUAGES. To employ the term *direct method* is to imply that some methods of teaching a foreign language are *indirect*. It is obvious that a direct method of learning to swim is to get into water of sufficient depth and move arms and legs to the desired purpose in the actual medium. An indirect method would be to take calisthenic exercises on dry land because there are somewhat similar bodily movements in swimming.

We employ the term *natural method* for the way a child learns his mother tongue as he listens to his elders make certain sounds in connection with certain objects, actions, and situations, and as he gets the idea and succeeds eventually in imitating the sounds with similar results. It is evident that this method of learning is direct, since no medium exists except the language being learned. A deaf-mute would learn directly also, except that his symbols would be visual, the only medium of expression in evidence to him, instead of aural.

Let us think, however, of a person who already has acquired a large set of concepts, each with its abstract symbol, both aural-oral (as he hears or utters the proper sounds) or visual (as he sees the printed symbols, whether or not he utters or *thinks* the sounds at the same time). If, when subjected to foreign speech in connection with objects, actions, or situations, he gets the idea and acts accordingly, then he has comprehended directly in the foreign medium. At first he must identify the idea with his own meaning-carrier, his native word uttered or conceived inwardly, unless it is a new concept, in which case the new word can very well become the meaning-carrier. When later he speeds up the process so that the foreign word (whether uttered or thought, however incorrect phonetically) carries the meaning with no reversion to the mother-language symbol, the learner is "thinking in the foreign language."

Suppose the person who is subjected to printed symbols in the foreign language in connection with objects, actions or situations, gets the idea and acts accordingly. He can see words on a sign in a show-window, for example, or point to the words on a menu and be served the desired foods in a restau-

rant. Direct learning has taken place; but the oral accompaniment, if any, has been according to previously learned phonetic systems. It is obvious that a person could learn a foreign language visually by direct method and verbalize it by his native symbols with results comprehensible only to himself. Nevertheless he could comprehend and act as well as a person who verbalized the symbols by the foreign phonetic system.

We must therefore divorce "direct method" from the requirements of an oral approach; it may be a visual approach as well. The "direct principle" is the same, however, for both approaches, namely that the medium of language experience must be the foreign symbols, even though the inward identifiers (in the learner himself; not expressed by the teacher or any accompanying agency) are in the mother tongue until the new symbols become sufficiently familiar by sight or sound to carry the meaning. Hence, we must hyphenate our terms and say "direct-oral" method (or "direct-aural" as we think of teacher or learner), direct comprehension of speech; or "direct-reading" method, direct comprehension of print.

It is clear then that by the direct method the learner must have an actual language experience without any preliminary study of grammar or phonetic (indirect method procedures). He must comprehend in terms of ideas and words he already possesses and connect the new symbols to the old concepts. If the situation is familiar and near to his experience, if easily recognized cognates and later, previously learned foreign words, provide contextual association, and if objects and actions dramatize words,—words capable of such dramatization—and if new words are suitably repeated, direct learning occurs. Out of this meaningful experience, grammar (the forms and relations of words) and pronunciation (the new verbalization) are organized inductively, practiced and assimilated.

If the teacher presents the new text solely to the learner's ear, the method is "direct-oral or -aural"; if the learner's eye may follow the printed text while the teacher presents the sounds to his ear, the act of reading is effected: the method is "direct-reading".

In the United States, the direct method in its oral approach has had a great vogue, at least in theory. It has compelled lip-service.

even though in practice it has not been entirely satisfactory. The theory may be sound, but conditions in American schools make its use difficult. In Europe, where it originated, teachers are well prepared in oral skills through travel and study in foreign countries, and the courses are long enough to secure good results (generally at least twice as long as the average in the United States). In the United States these conditions do not obtain. Since two years seems to be, rightly or wrongly, the accepted period for modern-language study, it is doubtful whether the direct-oral method is the best in the average situation. If used at all, conditions seem to require considerable adaptation to local circumstances.

In general, where the four-fold aim of reading, speaking, writing, and understanding is the accepted goal of foreign language teaching, some elements of the direct method are used, specially for the oral-aural skills. More often, some "oral practice" is used in combination with other grammar and reading procedures, as the occasion demands, the whole being called the eclectic or "complete" method. The *Modern Foreign Language "Study"* (q.v.), on the other hand brought the reading method into prominence with principles of learning no less direct, as the best method of attaining an early reading knowledge in the prevailing two-year foreign language course. (See MODERN FOREIGN LANGUAGES, TEACHING OF.) J.B.T.

DISABILITY—See HANDICAPPED CHILDREN; SPECIAL DISABILITY.

DISARRANGED SENTENCE TEST—See OBJECTIVE TESTS AND EXAMINATIONS.

DISCIPLINE. The term *discipline* refers to the quality or state of orderly individual conduct gained through training in self-control and in habits of obedience to socially approved standards of thought and action. This implies an adequate understanding of right conduct, the formation of desirable habits and attitudes, and ready adherence to such standards as are just and necessary. It

includes the socialization of behavior, the manner of working and living together, and the subordination of individual aims to group aims. It provides for individual as well as group welfare, encourages not only individual freedom but also the willing acceptance of necessary restraints, and enables one to acquire self-mastery as he grows toward the ideals of a democratic society.

This modern conception of discipline stands in rather sharp contrast to its traditional meaning. The difference between the two conceptions is less marked in their educational objectives than in the source and method of control. While both aim at good order in the classroom, the immediate aim, according to the older conception, was prompt obedience to the teacher's commands and unquestioning compliance with established rules and practices. Today the aim of discipline is the establishment of good habits, right attitudes, and the development of a wholesome personality and upright character in individual children. According to the older and more restricted meaning of discipline, control of conduct was external to the individual, imposed from without, sometimes by force. According to the newer and broader conception of discipline, the source of control is largely within the individual. Wise management and just government had the effect of producing good order, although imposed by the teacher. Now good order tends to be secured through cooperative control, guided experiences, the use of good judgment, and an abundance of democratic good will. This provides for much freedom in action and growth into liberty.

The changing meaning of discipline makes use of the positive rather than the negative aspects of control. According to the older conception, discipline was largely negative, in that attempts were made to secure and maintain control of pupil conduct through corrective measures, punishments, and restraints. Sometimes it was used to supplement or bolster positive controls. Such measures were educative only as they contributed to the reform of the offender. Used properly, they could be made an integral part of the school's constructive educational regime. Such usage, combined with the positive aspects of social and individual control, makes discipline constructive and gives it a new meaning. Phases of this combination, were

DISCIPLINE

the effective use of classroom management, individualized work and study activities, and all leisure and school-life activities which establish desirable habits or develop wholesome attitudes in children.

The newer conception of discipline is supported by studies of the learning and socializing activities of children. The findings of psychology indicate that children learn by experiencing, and that interest, freedom from worry, and satisfaction with one's work contribute positively to successful achievement. The child becomes self-reliant and self-controlled only as he has many opportunities to choose wisely and to act properly. Good behavior and self-control improve with practice in doing right things at the right time and in the right way. It is a wholesome discipline for children to do very hard things so long as they remain happy and successful in overcoming the difficulties which obstruct their purposes.

The psychological basis for discipline requires the individual to have many valuable mental and emotional as well as physical experiences. The mere performance of overt acts of a disciplinary nature is not sufficient. Acceptable participation in group life must be accompanied by ready acceptance and willing obedience to group standards to count for self-discipline. The individual must understand the justice of restraints placed on his conduct for a specific good purpose and agree that they are necessary and right. He must surrender voluntarily something personal for the sake of some greater gain accruing to him in due time. Cheerful compliance with established rules and willing adherence to one's consciousness of right are essential to wholesome self-discipline.

The social aspects of discipline are fully as important as the psychological. The child is a member of various class and school groups, clubs, and other organizations. In a democratically organized school group, pupil members are encouraged to participate effectively by helping to develop their conduct standards. Having done this, they accept responsibility for living up to them. When a member of a class group fails in this, the same group may disapprove of his conduct and restore him to his place of honor and respectability only after he has proved himself worthy. This teaches the value of cheerful obedience to group standards.

This illustration of social control within a school group reveals how indirect disciplinary control may become. The source of control is not so much in the immediate authority and influence of the teacher as in the regulations developed by pupils and the life and spirit of the school. A pattern for this is found in any well organized social center where the established ideals and customs of the community serve as proper controls of conduct.

With this change in the source of control, respect for the authority of the teacher remains an individual and social necessity. The teacher retains the responsibility for determining the limits within which child decisions may be made. He assumes the position of leader as he guides their discussions or advises them individually.

Today the teacher seeks to provide many opportunities for children to discuss conduct problems, to share in group thinking, and to make the choices and decisions of which they are capable. Such practice helps them to plan better for themselves and for each member of the group. It helps them to grow more independent in school and to gain in self-control.

While developing the ability to discipline himself, it is important that the child has purposes which he accepts, the accomplishment of which he regards as essential to his best interests. It is equally important that he has activities which he understands and in which he wishes to engage. Discipline becomes effective as he attempts to accomplish his purpose and attain the desired proficiency.

Some children are regarded as disciplinary problems. These pupils are usually the ones who differ from others of their group because of certain undesirable habits, personality traits, or behavior in the home, school, or community; whose conduct interferes, or is likely to interfere, with the individual's fullest development and usefulness socially, educationally, or hygienically; and whose behavior may result in more serious handicaps of one sort or another in later life. Many such problems have been created by the free and extensive use of force and external control to the neglect of training in right conduct and the practice of self-discipline. In this connection the teaching problem is one of reform. Its solution requires special treatment.

for each individual case. Some school systems provide special classes for disciplinary cases. Among them are classes for delinquent, emotionally unstable children, and socially maladjusted children. They are frequently organized in schools or school systems with a sufficient number of behavior problem children to form one or more classes.

The treatment of disciplinary problems today reflects an increasing tendency to regard misconduct as a symptom of maladjustment rather than merely as an offense to be punished. Though the educator and the mental hygienist do not deny that a specific instance of misconduct may sometimes have little psychological significance and that a recurrence of the incident can be prevented by the pupil's recognition of its unpleasant consequences, punishment alone usually is an inadequate way of modifying socially undesirable behavior patterns. Thus if an elementary school child is inattentive because the topic that is being discussed in class is far beyond his range of interest and his mental level, little lasting gain can result from giving him a low mark every time he is found to be inattentive. Similarly, if the adolescent boy who is emotionally insecure becomes a conceited show-off, annoying everyone by the air of superiority he displays but does not feel, the teacher's sarcasm will improve neither his personal adjustment nor his behavior.

This attempt at finding the causative factors which lead to misconduct and at planning the correction of serious disciplinary problems presents a challenge to the teacher and the psychologist. In some instances, the causes may be so involved that it may be necessary to employ the services of a child guidance clinic (*q.v.*). In other instances, the experienced teacher who understands children and is aware of their emotional needs and problems may be able to guide their readjustment without enlisting other professional assistance. While it is too much to expect that the teacher's use of intelligent disciplinary procedures will forestall the possibility of the student's becoming a neurotic, it is possible for a wise and sympathetic teacher to help correct emotional difficulties that otherwise would become an increasingly serious obstacle to wholesome living. (See MENTAL HYGIENE.)

Despite the emphasis which has been

placed on misconduct as a symptom of the pupil's personal difficulties, any corrective program that focuses attention solely on the child's emotional life may also prove to be inadequate. The correction and treatment of misconduct often necessitate other types of adjustments. Thus a method of teaching which presents little that is challenging to pupils or which makes little provision for stimulating pupil activity may be itself a cause of misconduct. Similarly, a curriculum that is largely unrelated to students' needs, interests, and abilities may be a source of conduct problems. The teacher need not become an amateur clinical psychologist to improve the discipline of his class; he often can accomplish more by being a better teacher.

Social forces, too, have their influence on discipline. The high school student who senses his family's need for his earning money may find it difficult to adjust to the high school which seems to stand between him and his conception of his duty. Such national crises as widespread unemployment or war are reflected in the attitudes of both teachers and pupils. The standards of the family and the demands of the gang may also create situations which lead to disciplinary problems.

Conduct usually is evaluated from the adult's point of view so that the child is considered "good" when he causes the adult, teacher or parent, a minimum of inconvenience. Some psychologists have objected to the use of conduct as a means of evaluating the child's adjustment to his environment because "good" conduct and "bad" conduct are often vague terms, the meanings of which depend on the adult and on the factors in the situation. Thus the same pattern of behavior may be considered good by one teacher and bad by another. Partly as a result of this changed attitude toward conduct, reports to parents now tend to omit any letter grade for conduct as though it were a distinct trait. Instead, there is a trend toward the substitution of a number of more specific and more descriptive expressions, such as "Works well with others." (See RECORDS AND REPORTS.)

Discipline today is viewed as a means of achieving fundamental educational goals. Good discipline is more than a means of getting students to learn more mathematics, to speak more effectively, or to understand French better. It may be a means of develop-

ing attitudes and personality traits that persist long after the more factual school learnings are forgotten. The teacher who has insight into child and adolescent psychology and the ability to get along well with his students has two of the most important assets that make for effective leadership in the classroom. It is small wonder, then, that good discipline and effective teaching are so highly correlated, for both stem from the same roots.

DISCRETE MEASURES—See CONTINUOUS MEASURES.

DISCUSSION METHOD. This method designates the give and take experience that is found in a live learning group. Questions are raised by any member of the group; answers are attempted by other members and are supplemented by still others, the teacher or leader included. The basic problems may well be raised by the teacher or leader.

The value of spontaneous and interested discussion lies in the fact that it implies vital learning activity; in fact, this type of discussion is the overt manifestation of vital learning.

The discussion procedure is exposed to a number of pitfalls. First, the teacher must make sure that the students have possession of the facts on which a profitable discussion may be based. Discussion is group thinking out loud and thinking can proceed only on the basis of adequate data. Without such data discussion is a mere beating of the air. A spirited preliminary discussion may well be used in raising problems, i.e., in the assignment, but before solutions are attempted, much careful observing, experimenting, and reading needs to be done.

The second danger is found in making discussion formal; having discussion for the sake of discussion rather than for the sake of learning. Unless discussion rises spontaneously in response to challenging problems, it had better be left alone. Too much precious time may be wasted.

The third danger lies in letting discussion go too far afield on tangents. All of us have attended meetings where about everything except the issue at stake was discussed. To hold the discussion to the point is not easy. What seems relevant to one may seem irrelevant to another. The teacher or leader must guide with his best judgment, remain courteous, yet firm.

A fourth danger is found in the difficulty of bringing a lively discussion to a timely close. Once a discussion has been well started, it tends to go on and on. Again the teacher must use his best judgment, be courteous and firm.

(See PANEL DISCUSSION.)

DISTRIBUTIVE EDUCATION. The larger department stores have had formal training programs for their sales workers for many years. Collegiate-level schools of retailing have been established at The Prince School in Boston, New York University School of Retailing, the University of Pittsburgh, and elsewhere. These schools, operating in close coordination with department stores, have been unusually successful in giving managerial and in-service training to distributive workers. These developments augur well for the ultimate establishment of merchandising as a profession.

DISTRICT SCHOOL SYSTEM

Numerous attempts have been made to establish salesmanship courses in the secondary school but they usually became formal academic courses and therefore the numbers enrolled soon dwindled. Since there are well over five million distributive workers in the United States, the desirability of school training for this area of service is evident.

The passage of the George-Deen Act in 1937 by the United States Congress has ushered in a new era of distributive education. Approximately \$1,200,000 has been made available to the several states for training in distribution. Within a few years this sum must be matched by the state and local governments. Therefore by 1947 approximately two and one-half million dollars should be available annually for distributive training. The federal regulations limit the use of this money to in-service and cooperative types of training programs. The initial stages of organization have now passed and, while most of the money is still being spent in department store training, increasing funds are being used in the retraining of small store merchants and clerks. This of course has necessitated a new technique of teaching and the development of new bodies of subject material.

DISTRICT SCHOOL SYSTEM. The district school system is the pioneer school organization in America. It was founded in colonial times to meet the needs of the widely scattered rural settlements for the establishment of small community schools. From these early beginnings it has persisted with some modification and is today the type of school organization most frequently found in rural areas. Although the district form of school organization has served a useful purpose in the past, there is a growing realization that a reorganization is necessary in order to provide the best educational facilities adapted to a growing complex civilization.

Size and Number. In 1933 there were 26 states in which the district was the basic unit of school administration. In these states there were about 119,000 school districts ranging in size from about five square miles in Illinois and New York to 360 in Nevada.

The average school membership per district ranged from 44 in Nebraska to 649 in Ohio. The number of teachers per basic unit varied from two in Kansas, Nebraska, South Dakota and Montana to 21 in Ohio.¹ It is thus apparent that when some of the larger cities are excluded, the district system is essentially a rural school organization maintaining one- or two-teacher rural schools and town and village schools.

District School. The district school is usually a one- or two-teacher ungraded school in rural areas or a graded elementary and high school in villages and towns. The United States Census Bureau classifies the population in the 'open country and in towns and villages of less than 2500 as urban. Using this classification as the basis, in 1936 the school population, children five to seventeen years of age, was about equally divided between urban and rural schools. The urban children were taught in approximately 27,000 schools; whereas the rural children were taught in 213,000 schools. There were about 364,000 teachers in the urban schools and about 461,000 teachers in the rural schools.²

Administration. The schools of the district are governed by a local board of education or school trustees usually elected by the people of the district. In many districts in rural areas the board of education administers the school directly, whereas in others, especially consolidated rural districts, villages or towns, a superintendent of schools is employed who carries on the duties of administration. Boards of education that administer their schools directly are usually assisted by county superintendents or supervisors employed by union or supervisory districts. Legally the board of education is the local governing body and has almost complete charge of the schools of the district subject only to statutory limitations. W.C.R.

DRAMATICS. Dramatics in education may be defined as the art of acting and producing plays by amateurs. It has long had a lively place in the schools both as a curricular and extracurricular activity. Courses in dramatics, dramatic art, or play production are found in the curriculum of the secondary school, where they are frequently offered as electives in the Departments of Speech or English. Colleges and especially universities of the present day often support departments in which a sequence of courses—such as Dramatic Interpretation, Play Production, Directing, and Stage Lighting—is offered. At both the secondary and higher levels extracurricular groups are fostered to produce one-act and longer plays. Such groups sometimes also produce pageants, which are written frequently by teachers and students in commemoration of an event or historical personage of special local interest.

In the elementary school various dramatic forms, including short plays, pantomime, and marionette and puppet shows, are used for public entertainment, assembly programs, and classroom aids. The vigorous growth of the activity program has caused an increase in the use of dramatic forms. For example, a progressive school may teach a unit in literature dealing with the Arthurian Legend by means of writing, costuming, and staging a play about King Arthur and the Knights of the Round Table.

At the other end of the educational age scale, adult education also makes much use of dramatics. Here, as at the other educational levels, dramatics are frequently resorted to as a means of raising money as well as for instruction and pleasure. Summer camps, settlement houses, cantonments, and churches are only a few of the organizations that make use of dramatics. In short, dramatics have become so important an educational activity that the term *educational dramatics* is well established in the vocabulary of educators and others.

Within recent years the educational world has witnessed the rapid growth of the dramatic tournament, an activity in which groups come together for the purpose of presenting plays in competition. If the tournament is large—covering a state, for example—elimination contests precede the final contest. The plays are judged and awards made to the winning groups. Dramatic tournaments have been initiated and promoted by Little Theatres, drama leagues, rural groups, universities, colleges, and dramatic fraternities.

Dramatics as an educational medium and activity are justified on many grounds. Doubtless they increase the self-direction of the participants and quicken their creative and appreciative powers. They tend, too, to deepen and widen interests as well as to identify particular individual abilities. As a successful dramatic performance cannot be realized without cooperation, the individuals concerned have to learn to work together to attain a common objective. Dramatics thus become an outlet for the worthy use of leisure time. Shy and diffident individuals, especially, may be helped in personality development through dramatics. Improved voice and diction, too, are frequent resultants. Certainly, dramatics provide the educator with an opportunity to challenge the student's imagination and intelligence. J.F.B-1

DRAMATIZATION — DRILL

College, New York, *Speech in College and Life* (an orientation manual), (Pitman Publishing Corp., New York, 1940).

DRAMATIZATION. Dramatization in education means the acting out of conceptions that are being studied by the pupils. It may be either informal and spontaneous or it may be formal, leading up to a carefully planned and rehearsed performance. It is the function of both to clarify understanding and to enrich emotional appreciation.

Informal dramatization, now frequently called dramatic expression, has an especial appeal to young children, but skilful teachers are using it to good effect throughout the secondary school, particularly in English and the social studies. Children get added meaning from imitating the work of the carpenter or the mailman, while a high school class gets both understanding and emotional appreciation by reliving the emotional intensity of the meeting between Grant and Lee at Appomattox.

Dramatization, in a narrower sense, means the writing, learning, rehearsing, and acting of a play. This consumes so much time and effort that it cannot well be used frequently, but, used at strategic points, its educative value may be high. Teachers may well plan to have every pupil take part one or more times in the writing and producing of a play before he graduates from high school. Dramatization leads not only to a vivid conception of subject matter but also to an insight into the drama, the theater, and the work of the playwright.

For maximum educative effect, the topics chosen for dramatization must lie within the subject matter studied. A high school class in English literature worked *The Lady of the Lake* into a play and gave it during commencement week. Everyone connected with the project considered the time and effort well spent. A sixth grade class in American history dramatized "The Settlement of Massachusetts". It is true that the writing and rehearsing of the play and the making of the costumes and scenery consumed much time, but the educative results were commensurate. The full understanding of early American history that was gained had a leavening effect throughout the course.

E. J. SWIFT, *Learning and Doing* (Bobbs-Merrill Co., 1914).

DRILL. Drill is the process of repetition to make automatic and permanent certain associations or responses. Drill follows the acquisition of understanding in order to facilitate the recall of those items we expect or desire to use habitually. A common misconception as to the meaning and purpose of drill is evidenced by such expressions as, "The pupils do not understand this; they need more drill." What is needed in such instances is not drill but assimilative experience—a variety of experiences out of which understanding comes. This is not drill, it is interpretative experience—analyzing, comparing, evaluating, and sensing relationships. When facts are comprehended they are partly fixed in mind, but they may easily fade out unless the associations are more firmly fixed by drill or through frequent use. The teacher's purpose in drilling is to assure the automatic or ready recall of associations needed for various reasons.

Drill should be distinguished from practice as a learning procedure, although they have much in common as forms of adaptation. In drill the terminal outcome is a mental association that can be reproduced automatically; in practice the terminal outcome is a motor activity or muscular coordination which is also freed from the necessity of conscious control. The term practice is also applied to the attainment of certain adaptive abilities like problem-solving, etc. Drill is concerned with the fixation of specific associations; practice is concerned with improvement of a motor coordination or application of knowledge. In drill the accuracy of the first associations is of crucial importance; in practice one begins with the approximate form or application and gradually perfects the adaptation. Thus, one *drills* on spelling, number combinations, content to be memorized, but one *practices* writing, drawing, singing, or the application of knowledge.

In carrying on drill, teachers should keep in mind the following factors that affect the efficiency of recall: (1) the accuracy of first impressions, (2) the vividness of the impressions, (3) the frequency of associations, (4) the recency of associations, and

(5) the effect of the learning experience, with respect to the pleasure or satisfaction derived.

To assure efficient drill activities, there should be effective motivation to secure proper attention and the readiness or "mind-set" conducive to maximum effort. This readiness hinges upon the pupil's realization and appreciation of his need for each particular drill. The proper choice of devices will contribute to the effectiveness of drill exercises. Where the material to be drilled on is not intrinsically interesting to the child, the teacher may use such extrinsic means of stimulating interest as keeping records of individual progress, playing educational games, as a form of drill, or enlisting the appeal of competition among groups of approximately equal ability.

Though drill has been thought of traditionally as being in terms of the group as a whole, it is becoming increasingly an individual rather than a group procedure. Since pupils vary in the degree to which various associations have been made automatic, there must be corresponding adjustment of the material to be drilled on. With the growing emphasis on individualized instruction, there is greater need for familiarizing the students, as well as the teacher, with the principles underlying effective drill and practice. In many schools the students are helped to understand and to apply such principles as these: (1) The student must be sure he understands the exact association before he drills. He should make prompt, accurate responses, but should not guess. A student who does not understand the forms of a verb conjugation in a foreign language, for instance, is not ready for drill on these forms. (2) A drill session should be a period of concentration without digressions or interruptions, which militate against habituation. (3) In a drill period there is usually learning under pressure. Where speed of response is desired, as in typewriting, the rate of response should be increased gradually but not at the expense of accuracy. (4) Drill should begin promptly and aggressively. (5) That method of recall should be used that is most appropriate for the particular associations as they are to be used. Thus, spelling should be drilled on by writing the words rather than by spelling them aloud. (6) Drill periods should be short and distributed over a considerable period of time. If the drill is prolonged too long, fatigue ensues. It is better to have students

form the habit of setting aside five or ten minutes daily for drill purposes than to rely on a longer period at the end of each week.

DRUG ADDICTION—See NARCOTICS.

DUAL SCHOOL SYSTEMS. A national system of educational organization that consists of two or possibly more schemes of educational institutions which parallel each other in terms of the age groups served but which provide different types of training is referred to as a dual school system. For the great mass of children and youth destined for unskilled, skilled, clerical, or minor administrative jobs, many European countries maintain a system of institutions which provides a rudimentary education, primarily in basic language and mathematical skills, followed by periods of vocational training in trade or continuation schools. The parallel system offers its pupils initial training in basic language and mathematical skills or it may take pupils after they have had such training through private tutoring or in the folk schools and then provide a training exclusively in academic subject matter, which is prerequisite for further study in the colleges, universities, or specialized technical schools. Pupils may transfer from the folk school system to the academic program in many countries, but only at an early age, usually when about nine to eleven years old.

In many countries, the dual system begins on the secondary level, or higher. For instance in Germany all children attend a *Grundschule* for the first four school years and then are placed into one of several types of secondary or continuation schools according to their aptitudes. In France the period of common schooling can extend up to the age of eleven or twelve, after which the more gifted children attend one of three types of secondary schools—the technical, modern, or classical—and the less gifted, a form of continuation school. In the U.S.S.R. the period of common schooling is extended until the children are fifteen years old when they enter apprentice schools, *Technicums*, or university preparatory schools. In Italy, the common schooling extends to the age of eleven for the less gifted and fourteen for the more gifted, after which differentiation begins. Dual systems extending all the way down to the earliest age can be found in England and in

Denmark, where a traditional private school system runs parallel with a newer public school system. The private school system originated as a system for the élite, distinct from that for the folk or common people.

There are many arguments for and against a dual system as compared with the prevailing ladder system of the United States. It is argued that a dual system based on a distinction between the classes and the masses is undemocratic; on the other hand, it is also true that a single ladder system of public education lends itself well to indoctrination by the political group in power. It is claimed that a dual system based on the ideal of putting each child into a school that will best train him along the lines of his aptitudes is more realistic; on the other hand it is claimed that the unitary ladder system is more flexible in that it seeks to discover aptitudes through guidance and a system of electives rather than to channel children into a path before their aptitudes can be truly discovered. However, the fact that most school systems are neither completely of the ladder nor of the dual type indicates that the trend is to make use of the virtues of each system. The trend in some European systems of raising the age of common schooling before differentiation begins, and the trend in the United States of introducing specialized secondary schools can be cited as examples of the merging of the two plans of educational organization. (See EDUCATIONAL LADDER.)

The term dual school system has still another connotation in the United States. Even though all of the states have compulsory education laws and public school systems, there are private schools at all levels. It is possible for a student, if he so wishes, to receive his entire education from kindergarten through the university in private institutions. Regarded in this light, education in the United States may be described as a dual system. However, because of state controls over the private schools in curricula and standards, it is generally possible for a student to transfer with little difficulty from one system to the other.

Attempts have been made by advocates of a single public school system to legislate non-public schools out of existence on the grounds that education in a democracy is a state function with its basis in the will of the electorate, and not a matter of individual prerogative.

However, the famous Oregon Case [*Pierce v. Society of the Sisters of the Holy Names*, 268 U. S. (510) (1925)] affirmed the opposing argument that primary control over a child's welfare rests with the parents, and that even though the state may require the parents to see that their children receive an education and attend school regularly up to a certain age, the parent has the right to choose whether his child is to be educated in public or in private schools. (See PARENTS, RIGHTS OF.) G.S.

DUAL TYPE OF ORGANIZATION OF SCHOOLS — See ADMINISTRATION, SCHOOL.

DUCTLESS GLANDS—See ENDOCRINE GLANDS.

DUPLICATING MACHINES. There are two principal types of duplicating machines in use in today's schools. The first of these, the mimeograph machine, utilizes a stencil made of thin fibrous paper coated with paraffin which is cut by the keys of the typewriter. This stencil is placed upon a rotating cylinder which allows ink to seep through the holes in the stencil so as to be transferred to the special mimeograph paper. The principal advantages of this form of duplication lie in the clarity of the copy and the large number of copies of material which may be run off from one stencil. The principal disadvantages of the mimeograph are the initial expense of the machine and the cost of the stencils.

The second type of duplicator employed in schools is of the gelatin type. With this duplicator the material to be reproduced is typed or drawn on the master paper with a special transferable ink. This master copy is then laid face down on a gelatin pad which absorbs most of the ink from the paper. Copies may then be made by placing paper briefly against the gelatin. The best gelatin duplicators also utilize a cylinder which is revolved by a handle, foot pedal, or motor. The principal advantages of this method of duplication are its relative inexpensiveness as compared with the mimeograph, the possibility of using a number of different colors on the same page, and the ease with which drawings and handwriting may be duplicated. Many workbooks and maps may be obtained

DYSPHONIA

ready-made for gelatin duplicators. The principal disadvantages are the limited number of legible copies which may be drawn from one master copy and the purple ink which is characteristic of typewritten copies.

The duplicating machine has become an accepted feature in most schools. It is used to provide copies of worksheets, laboratory and shop instructions, drawings, diagrams, charts, illustrations, tests, and, in many cases, school newspapers.

ECONOMIC GEOGRAPHY—See GEOGRAPHY, TEACHING OF.

ECONOMICS, EDUCATIONAL. The field of knowledge and research which embraces the problems lying between the two organized fields of economics and education. Rather than a combination of the two fields, educational economics deals with a specialized area lying at the border land between the two fields, and is somewhat comparable to such other specialized areas lying within or between organized fields as physical chemistry, mathematical physics, physiological psychology, economic history, social biology.

Some of the problems in the area of educational economics are the occupational distribution of workers; the training of workers for the various occupations; the amount and kind of specific vocational education needed; the relation of education to individual income and to the income of society; the relation of education to consumer problems—diets, housing, recreation, security; and others.

The field of educational economics is an appropriate one for students of educational administration and teachers of vocational education. Courses in this area are offered in teachers colleges and in colleges of education in universities.

ECUADOR, EDUCATION IN. Organization. As in almost all the Latin American countries, education in Ecuador is centrally administered. It is free and compulsory on the primary level. Schools that come under governmental control are lay and secular in character.

Educational facilities extend from the kindergarten to the university. The kindergarten has two grades and exists only in the principal cities. Primary schools are of two kinds, the rural primary school—the most common educational service—of four grades, and the urban primary school of six grades. Graduates of the primary schools interested in a secondary education have the choice of attending either the *Escuela Complementaria* (Continuation School) or the *Escuela Normal Rural* (Rural Normal School) if, for financial reasons, they cannot attend one of the *Escuelas de Enseñanza Media* (Intermediate Schools) in the urban centers: *Colegios de Segunda Enseñanza* (Secondary Schools) and the various Normal, Technical, and Professional Schools.

The *Escuela Normal Urbana* (Urban Normal School) offers a six-year course of study: four devoted to scientific and liberal studies, and two devoted to pedagogy and practice teaching. The *Colegios de Segunda Enseñanza* (Secondary Schools) follow the same plan and program as the *Normales Urbanas* during the first four years. The last two years are for specialization. The general baccalaureate degree does not exist. University education involves a course of study that may last from four to seven years depending on the requirements of the profession chosen. The University confines its activity largely to the preparation for the higher professions, and is little concerned with investigation and research.

The problems of greatest importance are the following: the necessity for balancing administrative centralization against the sharing

of power and responsibility with local organizations; the need of a board of education (*Consejo Superior de Educación*) to help the Ministry of Education in technical aspects of its work; the need for coordinating and unifying education from the kindergarten to the university; the achievement of greater stability and a more progressive spirit in education by freeing it from the influence of politics of the day; the need for a more comprehensive and generous educational budget, a need that will be realized more and more as the duty to liquidate illiteracy is understood.

Significant Educational Movements. Those educational movements of a political and administrative nature have generally been transitory, since the work of one regime has almost always been destroyed by its successors. Those brought about by professional and technical stimuli have had more lasting results.

Ecuador has had two German pedagogical missions—the first from 1914 to 1919 and the second from 1921 to 1924. The first introduced considerable reform in methodology in the primary schools which brought with it the rigorous formalism of the “*planes de las lecciones didácticas*” (plans for didactic lessons) favored by disciples of the sense realists. The second mission gave some impetus to the “*escuela del trabajo*” (activity school) but more in theory than in practice. Verbalistic teaching continued to hold sway. However, the enthusiasm and good will of teachers, strengthened by study and contact with the new education, have given renewed impetus to the active and practical orientation of the schools. The *Congresos Pedagógicos Nacionales* (National Pedagogical Congresses) have made excellent contributions to the development of education through discussions of vital problems. The influence of the ideas of Dewey, Kilpatrick, Washburne, and Kandell has been especially significant.

The influence of the United States has recently become very significant. While the structure of the educational system is mainly of French and Spanish origin, the practical and psychological orientation of the Ecuadorean educational leaders is in large part due to the influence of the United States. Teachers are encouraged to complete their professional training in the United States.

Numerous educators from the United States have visited Ecuador and left a deep impression. There exists an Ecuadorean Section of the New Education Fellowship of which Professor Julio C. Larrea is the first president. The *Inter-American Pedagogical Review—Nueva Era*—published in Quito, has enlisted the collaboration of many prominent educators of all countries of the Western Hemisphere and has attained hemispheric prestige.

Statistics. Ecuador has a population of three million. Its percentage of illiteracy is not large when compared with that of other Latin American countries. According to the latest report of the Minister of Education, there are among the children of school age (6-12) 101,351 literates, 95,682 semi-literates, and 130,209 illiterates. There are 3,114 primary schools in the republic, of which 2,470 are state, 342 municipal, and 302 private. The number of primary teachers is 6,404—4,489 state, 644 municipal, and 1,271 private. There are 19 Secondary Schools (*Colegios Secundarios*) with 416 instructors and 6,565 students, four Urban Normal Schools with 100 instructors and 1,284 students, four universities with 225 instructors and 1,885 students, two Higher Institutes of Pedagogy (*Institutos Superiores de Pedagogía*) with 33 instructors and 145 students.

EDUCATION, HISTORY OF — See HISTORY OF EDUCATION.

EDUCATIONAL AGE (E.A.). A subject age (arithmetic age, reading age, etc.) is a score, expressed in years and months, which corresponds to a given raw score on a standardized test in a particular subject. Thus, if a pupil's raw score on a standardized arithmetic test is converted into an arithmetic age of twelve years, his arithmetic score is equal to that of the average twelve-year-old. When a battery of achievement

tests is administered, the various subject ages may be averaged and expressed as the *educational age* (also called the *achievement*, *accomplishment*, or *attainment age*), which can be used to compare the pupil's average ability in the various subjects with that of other pupils.

When the pupil's educational age is divided by his chronological age, we get his *educational quotient* (*E.Q.*), which is a means of evaluating his average achievement in comparison with that of others of the same chronological age and is thus a measure of the rate of educational progress.

Similarly, the pupil's achievements may be evaluated in terms of his mental ability. The *achievement quotient* (*A.Q.*), sometimes termed the *accomplishment* or *attainment quotient*, may be computed by dividing the pupil's educational quotient by his intelligence quotient, or by dividing his educational age by his mental age. The latter method of computing *A.Q.* can be used only when both ages have been determined on approximately the same date; in other cases, the educational quotient and the intelligence quotient must be used. If a pupil's *A.Q.* is below 100, his achievement is not so high as the average of pupils of his mental level. If his achievement quotient is above 100, he is working above the average of pupils of his mental level. To some extent, *A.Q.*'s above 100 result from inadequate norms for the subject matter tests used. (See *NORMS*.) J.J.

EDUCATIONAL CLINIC—See **CLINIC, SCHOOL**.

EDUCATIONAL CORPORATION. The public school is a state institution, completely and solely subordinate to the plenary power of the state legislature, subject to state constitutional limitations. The state can create and dissolve school districts at will, and without the consent of the inhabitants who gain no vested rights against the state in any one form of organization. The state may alter district lines, redistribute district property, grant and withhold state school moneys, and dictate internal district organization or type of school board membership. Neither the

school district nor its inhabitants have any rights to any form of school organization except as given by the state legislature.

When the state sets up a school board, it almost universally (although not necessarily) sets it up as a separate corporation, distinct and apart from the municipal organization (city, etc.) within which it may be found. Legal proceedings involving the school must be brought against the school board as a separate legal entity, an educational corporation, and not against the municipality. The school officers, whether elected or even if appointed by local municipal officers, are state officers.

Basic to all discussions of the status of the school corporation, therefore, is the fundamental legal concept that the school board or school corporation is a creature of the state, subject, in all regards short of constitutional limitations, to state control and mandate.

EDUCATIONAL FOUNDATIONS—See **FOUNDATIONS, PHILANTHROPIC; FOUNDATIONS OF EDUCATION**.

EDUCATIONAL GUIDANCE — See **GUIDANCE**.

EDUCATIONAL LADDER. The system of education in the United States has been referred to as an educational ladder because the various levels of the school system are open to virtually all the graduates of the next lower school. Thus, in the United States, all children attend the elementary school regardless of whether they will become members of a learned profession or unskilled laborers. Similarly, all elementary school graduates may enter the secondary school. Theoretically, at least, the various rungs of the educational ladder, from the primary grades to the university, are open to all pupils who have the requisite ability and interests. This educational ladder is in sharp contrast to the dual school systems (*q.v.*) found in many other countries where the kind of elementary education to which the child is admitted may determine the type of schools for which he will be eligible in later years. Some elementary school graduates, for example, may never be able to pre-

EDUCATIONAL LADDER

pare themselves for higher education simply because of the kind of elementary school they have attended.

Although education in the United States is a state rather than a national responsibility, the educational organizations found in the various states usually follow a similar pattern. The educational system of this country consists of a single common school program beginning at ages four to six, depending on the provision of nursery and kindergarten grades, through eleven or twelve years of schooling in an administratively integrated system of elementary, junior, and senior high schools, climaxed by college, university, or professional school. Admission to each administrative unit is based on completion of the required work in the preceding unit, and no discrimination in admission is made on the basis of social, economic, or political standing. A complete system of education through the secondary level is publicly supported and controlled in all the states, and most states also provide for higher education at publicly supported institutions.

The democratic spirit expressed in the educational ladder continues to dominate education in the United States—all primary grades children do climb the first rung of a ladder that leads to the university—but the increasing differentiation of educational institutions makes the educational ladder an inadequate symbol of public education. In some of the larger cities the elementary school graduate may choose from so wide a variety of secondary schools that it is inaccurate to depict the secondary school simply as a single rung on the educational ladder—above that of the elementary school and below that of the college. The graduates of some specialized high schools, for example the vocational high school, are as ineligible for admission to a liberal arts college as are the graduates of some European secondary schools ineligible for entrance to the university.

Even for those students whose abilities and interests are along academic lines, there have been so many changes on the elementary and secondary levels that the picture of a ladder gives an erroneous impression of the successive steps they take as their education progresses.

In the latter part of the nineteenth century, the predominating system was the 8-4

plan, eight years of elementary school followed by four years of secondary schooling. However, each of the two types of schools had developed along such distinctive lines in curriculum and methods of teaching that there was a conspicuous lack of articulation between the two, and the gap between the elementary school and the high school brought with it mounting problems of pupil maladjustment and consequent educational waste. In addition, it was felt by educators and psychologists—President Eliot of Harvard, G. Stanley Hall, John Dewey, and many others—that the secondary period of schooling should begin earlier. A 6-6 plan was advocated which would shorten the elementary school period to six years and start the secondary school two years earlier. However, during the period from 1900 to 1909, the emphasis shifted from the 6-6 to the 6-3-3 plan in which a separate intermediate organization, the Junior High School, was inserted between the elementary and the high school. This idea, actually the first variation of the old 8-4 system to find widespread application, found rapid favor, until in 1938 about 32.1% of the pupils enrolled in secondary schools were enrolled in a divided junior and senior high school plan (6-3-3 and variations). Since 1934, however, the trend seems to be toward the earlier 6-6 system, or undivided junior-senior high school and the number of students enrolled in such systems is steadily increasing (from 18.9% of the students in secondary schools in 1934 to 24.4% in 1938). In spite of this emphasis on the reorganization of education, the percentage of students enrolled in the traditional 8-4 plan remains higher than in either the 6-3-3 or 6-6 plans, even though it is decreasing (from 51.2% of the students in all secondary schools in 1934 to 43.5% in 1938).

Another earlier variation was the 7-4 plan, which reduced the total elementary-secondary span from twelve to eleven years on the theory that educational waste in the elementary school could best be lessened by shortening that period one year. For a time in certain Southern states this plan was in wider use than the 8-4 plan. The schools of Salt Lake City revived interest in this plan in 1926 when they changed from a 6-3-3 to the 7-4 plan.

The problem of lack of articulation be-

SOME VARIATIONS OF THE EDUCATIONAL LADDER.

tween the secondary school and the college led to plans of reorganization on the upper level of the ladder similar to those on the middle level. With the introduction of the junior college (*q.v.*) and its variations, the traditional 8-4-4 plan (the 8-4 plan plus a four year college) was replaced in some places by the 6-3-3-2 (six year elementary school, three year junior high school, three year senior high school, and two year junior college), 6-6-2 (six year elementary school, six-year combined junior-senior high school, two year junior college), and the 6-4-4 (six year elementary school, four year junior high school, four year combined senior high school-junior college) plans, to each of which two years of "senior" college are added above the junior college. A 6-8 plan, in which an eight year secondary school covers all levels from junior high school through junior college, is a recent addition (Pasadena, California).

The trend seems to be away from the multi-school system as exemplified by the 6-3-3-2 plan toward one of fewer units, such as the 6-6-2 type. However, it must be remembered that no one plan has as yet assumed dominance over the traditional 8-4-4 organization. What the system of the future

will be is difficult to predict. Some educators have even ventured to predict that with vertical expansion (the addition of kindergarten and nursery school) the prevailing type of the future may be a 4-4-4-4 (four years of early childhood education, four years of elementary education, four years of high school, four years of community college) with "senior" colleges and professional schools for those who have completed the sequence. (See also ELEMENTARY EDUCATION; JUNIOR HIGH SCHOOL; SECONDARY EDUCATION; JUNIOR COLLEGE; LIBERAL ARTS COLLEGE.)

EDUCATIONAL LAW AND LEGIS-

LATION. Perhaps to a greater degree than with most other governmental functions, the legal status of the school has been developed in the halls of legislatures rather than in courtrooms. Owing to the nature of the relationship between the federal and the state

governments, whereby the federal government was one of delegated powers and the state government of residual powers, education traditionally has been a state function in the United States. The state legislature, as the repository of the power of the people of the state, in the absence of constitutional provisions to the contrary, was the natural place to seek for legal clarification of the school's position.

It is fundamental American law, therefore, that subject to constitutional restrictions, the state legislature has plenary and complete power over the school, both as to ends to be accomplished and the means with which they are to be accomplished.

However, there are certain constitutional limitations upon the otherwise plenary power of the legislature. The Federal Constitution has placed some restrictions upon state action in general which are applicable to legislative action in school matters. For example, the Fourteenth Amendment provides, in part, that "no state . . . shall deprive any person of life, liberty or property without due process of law". The Supreme Court of the United States has frequently invalidated educational legislation on the ground that the state abridged someone's constitutional rights without "due process of law". For example, when Oregon attempted to compel all children to go to public schools, thereby legislating out of existence all parochial schools, the Supreme Court declared the statute unconstitutional as unduly abridging the rights of parents to make a choice among schools (*Pierce v. Society of the Sisters of the Holy Names*, 268 U. S. 510 [1925]); and when the state of Nebraska, in common with some ten other states during the First World War, attempted to forbid the teaching of foreign languages in public or private schools, the Supreme Court ruled the legislation invalid as depriving both parents and teachers of their liberties without due process of law. (*Meyer v. Nebraska*, 262 U. S. 390, 43 S. Ct. 625 [1923]); on the other hand, statutes requiring all students to submit to vaccination were held not to be in contravention of constitutional rights (*Jacobson v. Commonwealth of Massachusetts*, 197 U. S. 11, 25 S. Ct. 358 [1905]).

Another Federal constitutional guaranty is the contract clause, providing that no state may lawfully impair the obligation of con-

tracts. In the famous Dartmouth College Case the Supreme Court held that a royal charter to the college, being a contract, could not be revoked by the state (*Trustees of Dartmouth College v. Woodward*, 4 Wheat. 518, 4 L. Ed. 629 [1819]). More recently, the Supreme Court held that the state of Indiana could not repeal a statutory teacher tenure act that had become contractual in nature (*State ex rel. Anderson v. Brand*, 303 U. S. 95, 58 S. Ct. 443 [1938]).

Still another Federal constitutional guaranty is the equal protection clause, providing in substance that all citizens must be treated equally and without discrimination. Under the aegis of this clause, the Supreme Court has recently held certain wide-spread state legislative practices as unconstitutional for failing to provide equal facilities for Negroes in publicly-endowed professional schools. (*Missouri ex rel. Gaines v. Canada*, 305 U. S. 337, 59 S. Ct. 232 [1938].)

Apart from limitations to be found in the Federal constitution, there may be some restrictions in the state constitution, common among which is the mandate that the legislature provide for the establishment and maintenance of a uniform system of public schools.

Nevertheless, subject to constitutional limitations, the state legislature has supreme and plenary control over the school system. It may determine the ends of education, in terms of the curriculum, the type of schooling, the textbooks to be used, or the type of student admitted. It has similar complete control over the means to be used for achieving the ends it has set up: means of financing (ranging from complete state support to no state support), the qualifications of teachers and of students, obligations to non-residents, election of officers, mode of contracting, type of building, and other such basic considerations.

Statutory development of the school system has been along two distinct but related lines: direct legislative action, and delegation of authority to make rules and regulations to a state school board or state superintendent. It is well to remember, furthermore, that not all school legislation appears in the school code; important provisions may crop up in the penal law, the election law, civil rights law, and other seemingly unrelated laws of a more general application.

Educational legislation has reflected the American tradition that the schools belong to the people, not to the educators. State legislators, consisting as they do of elected representatives of the people, have therefore acted not only on such general problems as the organization of the school system, the age to which education should be compulsory, and the type of teacher to be employed, but also on such technical questions as the content of the curriculum. Teachers and administrators, who should presumably be qualified by training and experience to decide curricular questions have been told, by means of legislation duly enacted, that they may not eliminate certain subjects from the curriculum, for example community civics, or even certain topics, such as the effects of alcohol. Similarly, some school systems have been forbidden to include certain subjects, for example, evolution or communism. Though most American educators regard it as perfectly proper for legislatures to act on broad questions of public educational policy, there is increasing objection to legislation which concerns administrative or pedagogical problems which can be solved better by professional educators than by legislators who may be more responsive to political pressures than to the findings of educational research.

EDUCATIONAL POLICIES COMMISSION. When the National Education Association and the American Association of School Administrators jointly established the Educational Policies Commission in 1935, they assigned it the following functions: the stimulation of thorough planning by the teaching profession over a period of years; the promotion of progressive changes in educational theory and practice; the evaluation of suggestions for improvement of education; the extension of knowledge and use of the best practices throughout the country; and the improvement of cooperation among groups contributing to educational progress. During the short life of the Commission, it has made a profound impression on the thinking and procedure of the teaching profession and has influenced to some degree the lay public.

The Commission has published some books for the purpose of expressing its philosophy of education and recommendations of teaching procedures. The best known of these books are probably those constituting the American democracy series: *Unique Function of Education in American Democracy*; *Purposes of Education in American Democracy*; *Structure and Administration of Education in American Democracy*; *Learning the Ways of Democracy*; and *Education of Free Men in American Democracy*.

In 1939-40, the Commission sent a staff of six men to make a study of civic education as practiced in ninety secondary schools in twenty-seven states representing different parts of the United States. The report of the findings, containing case studies of actual practices in the schools, is in the book, *Learning the Ways of Democracy*, which is among those listed above. To carry the recommendations of this book to all parts of the United States, the Commission has held several regional conferences.

EDUCATIONAL PSYCHOLOGY. Educational psychology had its beginnings in the attempt to apply to a number of educational problems the results and techniques developed by psychologists in their investigation of mind and behavior. It soon came to constitute a separate field, particularly as empirical methods were developed to compare various methods of teaching, to trace the development of the child, to measure abilities and personality traits, and to discover environmental influences on learning and behavior. Historically, the central topic of educational psychology is learning—its nature, antecedents, conditions and results.

Since educational psychology is meant to form part of the professional training of teachers, a good text on the subject offers to teachers principles of guiding the learning process in such a way that the outcomes de-

sired will eventuate, in so far as possible. Educational practice, however, cannot be founded upon educational psychology alone. Though, as a result of research carried on in close contact with the school, educational psychology has suggested many innovations and changes in practical education, it cannot determine the aims of the school nor the environmental factors which actually exist.

Experiments in educational psychology prove futile if they do not relate to actual purposes and conditions. With changing emphases in educational objectives, much of the older experimental work and the generalizations derived therefrom have become obsolete. Principles of learning with respect to the memorization of verbal facts will not apply to the solution of problems or the development of initiative. There is the added fact that psychological research, both in its techniques and particularly in its conclusions, is always influenced by psychological theory at the same time that it itself modifies psychological theory. This means that texts in educational psychology, though referring to research experiments for their evidence, may be quoting conclusions based on a psychology that is no longer held, or about which there has arisen much controversy. The student often must learn, therefore, how to reinterpret the data presented. In any case he must beware of looking only for specific conclusions in a field where principles have not been established in such a universal fashion that they can be stated as "laws." The references given below are recent books with somewhat varied viewpoints and not completely overlapping content in the topics treated. (See such articles as CHILD PSYCHOLOGY; INCENTIVES; INTELLIGENCE; LEARNING; MENTAL HYGIENE; and PSYCHOLOGY OF SCHOOL SUBJECTS.)

EDUCATIONAL QUOTIENT — See EDUCATIONAL AGE.

EDUCATIONAL SOCIOLOGY. One of the academic fields basic to the systematic study of education. Its general area is the relationship between society and the education process, and as such it complements the general area of educational psychology which is concerned with the individual human organism in its learning aspects. Both these areas provide objective data upon which a third major field, educational philosophy, must build its speculative search for desirable human values to be sought through education.

Two conceptions of educational sociology may be distinguished in its scanty literature: (1) the theoretic: that it constitutes primarily a socialized educational philosophy, seeking to relate educational programs more closely to life needs, and (2) the scientific: that it is essentially a social science, striving to discover empirically its own body of data and operational principles which may then be applied to the problems of education. Conflicting as these orientations may appear, they nevertheless represent two facets of one common interest in the relationship, actual and desirable, which exists between the educative process, broadly conceived, and the larger society of which that process is an integral aspect.

The field of educational sociology is therefore devoted to description and analysis of those factors, agencies, and influences which contribute—formally or informally, deliberately or accidentally—to the socialization of the individual. Specific attention is frequently given to such broad sub-areas as the social significance of education; the functional interrelationship of education with other institutions; the influence of environment upon individual and group behavior; the family, church, press, movie, government, economic system, and other institutions as educative agencies; the rôle of the school as a specialized agency in the total educative process; the effects of various societal forces and factors upon school aims, curricula, methods, organization, and control; the relationship between education and social progress; and the like.

Although educational sociology is a relatively undeveloped field and one not yet widely recognized in the professional curriculum, its influence upon educational policies and programs at all academic levels is

marked. Directly based upon its findings are such recent educational developments as the determination of school aims through life-activity analysis, the core curriculum (*q.v.*), the utilization of community resources for purposes of instruction and the cultivation of desirable attitudes, the participation of youth in community service projects and in programs of work experience, and the community school. (See COMMUNITY and SCHOOL.) These and many similar achievements during the past two decades have resulted from the work of educational sociologists, who have documented and demonstrated the intimate relationship which always exists between societal mores, human needs, and educational imperatives.

EGOISM. All human beings want to achieve some measure of distinction to enhance and perpetuate their ego (concept of self). This urge is called *egoism*, or it may also be referred to as egocentricity, self-esteem, self-regard, self-love, self-importance, or self-seeking.

The small child is very egocentric, especially before the age of three. This is shown by his language—use of imperative sentences and self-words—and by his social behavior, e.g., his desire for the exclusive possession of toys, his tendency to grab things away from others, threatening, teasing, and rivalry for the affection and approval of other children and adults. Jealousy and negativism are also evidences of a desire for mastery (See NEGATIVISM). Under ordinary circumstances extreme egoism declines with increasing matur-

ity and social experience, and the goal of individual adjustment is a balance between egoistic and altruistic tendencies. However, many children and adults who are unable to satisfy their ego directly, resort to various types of artificial mechanisms, such as blaming others for their failures (projection); trying to justify selfish behavior by offering altruistic reasons (rationalization); excessive boasting about abilities or exploits (over-compensations), or seeking satisfaction in imagination (phantasy).

In reality much of what is commonly called "ambition" has its basis in egoism, and is socially desirable if not developed to excess. Individuals show egoism in choosing vocations which will enhance their self-regard, even when these may not be best suited to their needs and abilities. For example, girls sometimes insist upon entering the teaching profession because of its supposed prestige, when they would be more successful in clerical or sales jobs. Another illustration of the power of egoism is seen in the Oriental's desire to "save face" at almost any cost. Thus, if a Chinese child is punished in school, his entire family "loses face", and he must do something to restore their self-esteem.

In modern society, well-adjusted individuals must find acceptable ways to build up their feeling of self-regard; they must not only avoid deflating the egos of others, but must help them to develop self-esteem. (See MENTAL HYGIENE.)

EIDETIC IMAGERY. A visual *eidetic image* is a vivid and detailed mental image projected outside the head, usually onto a dark-gray surface after the stimulus, like a picture, has been looked at with roving eyes for about thirty seconds and then has been removed. An eidetic image is said to have an after-image and a memory-image component but to be a phenomenon distinct from both. Like an after-image, an eidetic image reproduces accurately many details, such as the exact number of spokes in a carriage wheel, but it lasts longer, appears often in positive

rather than complementary colors, and may change spontaneously or voluntarily in size, shape, and manner of appearance and disappearance. Like a memory-image, an eidetic image is influenced in content by the interest of the subject and by other central factors, such as perservation, but it lasts longer, is projected outside the head, and is accompanied by incomparably stronger tension and pressure on the eyes in spite of roving vision during exposure. Eidetic imagery differs from hallucination in that the subject does not confuse it with reality. The spontaneous remarks of the subject are surprising even to himself. Moreover, the behavior of adult subjects gifted with eidetic imagery is fundamentally the same as that of eidetic children.

The consideration of eidetic imagery as a distinct perceptual phenomenon is open to question. Exhaustive check experiments have failed to confirm the "laws" of behavior posited for eidetic imagery. Final judgment as to whether it cannot be dissolved into specialized forms of after-imagery and memory-imagery, at present little understood, must await the development of adequate controls independent of the subject.

Under the direction of E. R. Jaensch of the University of Marburg, Germany, systematic research in eidetics has concentrated on contributing to the psychology of perception, education, and the concept of personality or constitutional types, and to the building of a self-contained philosophy and cultural anthropology. The disciples of Jaensch have conducted extensive but uncontrolled experiments on the relation of eidetic imagery to learning and achievement. It is claimed that Eidetiker are more creative in art, write more vivid compositions, and react imaginatively more deeply to literature rich in visual imagery, than do non-Eidetiker. They are presumed to learn spelling and arithmetic more readily by projecting images onto the paper. The writer's own controlled check experiments on Eidetiker and non-Eidetiker, paired for chronological age, verbal intelligence, and reading level, failed to reveal any significant differences, educational or statistical, as to the learning of spelling, quality of written composition, appreciation of imaginative literature, or scholastic achievement. Eidetiker accompanied their perceptual thinking, learning, and creation with emotionally toned

imaginal illustrations, which did not influence the quality of their output as measured by available instruments of evaluation.

Jaensch divides Eidetiker into two personality or constitutional types, the *Basedowoid* and *Tetanoid*, on the basis of somatic differences—like lustrous protuberant eyes, symptomatic of exophthalmic goitre—and of predominance of the after-image or memory-image component of the Eidetiker's imagery. Check experiments on the syndromes of both diseases, Basedow's (goitre) and tetany, have failed to validate the physical criterion. However, the exploitation of typological methods in research on eidetics is a contribution to the psychology of perception. The philosophical and anthropological theories based on eidetic imagery are highly speculative. S.S.

EIGHT YEAR STUDY OF THE PROGRESSIVE EDUCATION ASSOCIATION. During the first quarter of the century the curriculum of leading elementary schools had undergone marked change. Corresponding change in the secondary school was partly inhibited by the fixed nature of the entrance requirements of many colleges. In the meantime the proportion of American youth attending secondary schools increased phenomenally. The American high school was becoming a school for the entire range of the adolescent population, youth with widely varying abilities, interests, and purposes. Although less than a third of the high-school graduates went on to college, college requirements in large measure determined the school curriculum. Freedom to experiment with the development of a curriculum better adapted to the contemporary student population required the cooperation of the colleges. Hence, the Eight Year Study was organized by a directing committee of school and college representatives with Wilford M. Aikin as chairman, and a group of thirty schools of various types and sizes scattered from Massachusetts to California was chosen. Begin-

ELECTIVE SYSTEM

ning in 1933 each school was free to experiment for eight years with its own hypothesis regarding the kind of curriculum most effective for its students. Most of the nation's colleges agreed to admit graduates from these experimental programs without prejudice to the fact that they had not met the usual college entrance requirements. The directing committee maintained a staff of curriculum consultants and an evaluation staff to assist the schools in appraising the results of the experiment.

The evaluation staff compared the college records of graduates of the experimental programs with those of a matched group of students who had met the usual college entrance requirements. The graduates of the experimental curricula were slightly superior to those of the matched group; furthermore, the graduates of the six schools that had made the most comprehensive reconstruction of their curricula were considerably more successful both in academic work and in extra-curricular activities than the matched group which had followed the usual high-school curriculum.

The Eight Year Study showed conclusively that the secondary-school curriculum could be reconstructed to provide more adequately for the wide range of high-school students without decreasing its effectiveness in preparing students for college. The investigation also identified certain principles upon which the more effective curricula were built, and developed many evaluation instruments by which some of the more intangible results of education may be appraised.

Among the methods for facilitating school-wide cooperative curriculum reconstruction developed in the course of the project was the summer workshop, which provided opportunity for groups of teachers to work on their problems for a period of six or eight weeks with the aid of a selected staff and the facilities of a large university. (See TEACHERS' WORKSHOP.) The effort to evaluate the progress of the students in a systematic and comprehensive fashion also proved to be a powerful instrument for guiding curriculum revision. Finally, the study demonstrated the value to teacher motivation and morale of participating in educational experimentation, and has led to a series of similar projects

among groups of secondary schools throughout the country.

ELECTIVE SYSTEM. The elective system refers to the plan of permitting college students to elect the courses they study. The most significant period of the development of the elective system was in the last three decades of the nineteenth century because of the then increasing number, importance, and extent of new courses, especially in the sciences and social studies. Since previously almost the entire curriculum had been prescribed, the only way to give new courses their proper prominence was to make certain older courses elective. Beginning about 1870 Harvard, under Charles W. Eliot (q.v.), led the experiment against considerable opposition. By 1884 the only required courses at Harvard were for freshmen, and even most freshman courses were elective. Other colleges adopted a similar, though somewhat more restricted, system. The thoroughgoing elective system, however, meant that in large colleges a student could graduate after four years of freshman courses. In the early years of this century, this fact and the increasing need for specialization led Harvard and then other colleges to the still prevalent practice of requiring a student in his last two years to concentrate in some one "major" field and one or two "minor" fields, and to use his first two years in "distribution" of his effort among several curriculum divisions. Yet, except where survey courses are required of all students, students today usually elect many of the courses they study both in the divisions of "distribution" and in "major" and "minor" fields. But the tendency to map out a four-year program of required courses is still strong, as is evident in the curricula of such new fields as home economics and business.

The major value claimed for the elective

ELEMENTARY EDUCATION

system today is that it offers a convenient procedure for adjusting the college curriculum to the needs and interests of individual students. On the other hand, there are few educators today who have so much faith in the student's intellectual maturity that they are ready to give him the complete responsibility for planning his college course. In general, the student at a liberal arts college has much greater freedom of choice of electives than has the student attending a professional course.

Although the elective system is also found in secondary schools, there the student's freedom of choice is usually greatly restricted; for example he may be required to study a foreign language, but he may choose the language to be studied; or he may elect another science instead of another foreign language. The typical secondary school curriculum consists largely of prescribed rather than elective work.

The future of the elective system depends upon that of curriculum and methods. Encouraging the individual student to elect, under guidance, initial problems, as well as to determine his own general pace and procedure of study—but only within certain broad, required curriculum divisions—may suggest the proper amount and kind of elective and required studies. Until colleges have far more experience with individualized instruction and various kinds of curriculum divisions, however, a great variety of practices is inevitable. M.G.F.

ELEMENTARY EDUCATION. Aims. Traditionally limited to mastery of the Three R's, the aims of elementary education have been broadened in recent years to comprise the furtherance of all aspects of wholesome growth and development of children. There has been a gradually increasing acceptance of responsibility for the development of physical and mental health, worth while leisure interests, social adjustment, emotional balance, the higher intellectual abilities, and the habits and attitudes that promote democratic living.

Organization and Administration. About 1840, the common or elementary school in the United States began to take shape as one comprising eight grades, except in some southern states where a seven grades school was the rule. Since 1860 the kinder-

garten movement has led to the addition, in many schools, of a year's schooling for five-year-olds preceding Grade I, and in some a junior kindergarten of one-half year for children four and one-half years old. In 1938, however, only 650,000 pupils, representing less than one-third of the five-year-olds of the country, were enrolled in kindergarten. Since 1910 the development of the junior high school has resulted in the classification of many seventh and eighth grade children in the cities as secondary school pupils. However, more than two-thirds of the seventh and eighth graders of the nation are still attending elementary schools.

The 220,000 elementary schools of the nation include 120,000 one-room buildings. The number of one-teacher schools is gradually being reduced through the consolidation of schools and the transportation of pupils to larger educational centers. In 1938, 22 million pupils attended elementary schools, ninety per cent being enrolled in public schools, ten per cent in private schools. All but some two per cent of the private schools were under church control, being chiefly Catholic, with a small minority of Lutheran schools. (See LUTHERANS, EDUCATIONAL WORK OF; ROMAN CATHOLIC EDUCATION.)

The principal (*q.v.*) is the administrative and supervisory head of the school, assisted in his supervisory duties by such city or rural supervisors as are available. The status and importance of the principal as the educational leader of the school have improved markedly in recent years. There is at present a significant trend toward a more democratic participation of the whole school staff in defining the goals and solving the problems of the school. There are some 21,000 elementary school principals, of whom one-third are men and two-thirds women. Of city school principals, some forty per cent devote full time to administrative and supervisory duties, while nearly sixty per cent are teaching principals.

Curriculum. The elementary school curriculum may be thought of as comprising (1) the basic skills of language, reading, writing, spelling, and arithmetic; (2) the content subjects of science and social studies (history, geography, citizenship); and (3) the expressive arts of music, painting, drawing, and bodily movement. A survey in 1936 indicated

that almost half of the school day was devoted to work in the basic skills, one-sixth to social studies, and slightly more than one-third to art, music, physical education, and the other so-called special subjects.

Whereas the curriculum was formerly thought of as merely certain skills and subject matter to be learned, the present tendency is to consider it as comprising all the activities and experiences that children have through their attendance at the school. Another trend is toward increased integration or correlation of the program; activities in the content subjects provide needs and incentives for mastery of the Three R's, and the expressive arts furnish outlets for ideas, insights, and emotions derived from study in the content areas. (See ACTIVITY PROGRAM.)

Methods. Since 1910 especially, methods of teaching have been and still are being improved continually through widespread research and experimentation. Increased instructional efficiency has resulted also from better preparation of teachers, improved classification of pupils, more discerning analysis of pupils' needs, progressive improvement of teaching and learning materials, and increased recognition of the factors of maturation and readiness in learning. There is increased emphasis on enlisting the aggressive cooperation of pupils in their own education by appealing to motives and purposes that they can accept as significantly worth while, in contrast to earlier practices of imposing "bookish" subject matter on reluctant pupils.

Standards. The average school year in the United States is approximately 170 days, ranging in different states from 130 to more than 180 days. Former attempts to enforce rigid and uniform standards of attainment on all pupils for promotion from grade to grade and for graduation have by and large been abandoned in view of the tremendous individual differences among pupils which modern research has revealed. Frequent use of informal and standardized tests to reveal pupils' specific needs as well as accomplishments has largely replaced the earlier administration of uniform examinations on a county-wide or state-wide basis as hurdles to further schooling.

Teachers. Some 660,000 professional workers serve in the elementary schools of the United States. Twelve per cent are men

and eighty-eight per cent are women. The preparation of these teachers ranges from high school graduation to graduation from college. The bachelor's degree is required for elementary school certification in five states. It is estimated that three-fourths of the elementary school teachers have at least two years of college work. Salaries vary with the level of preparation demanded, the average for the United States in 1936 being \$882 per annum. Teachers in the elementary schools generally receive less compensation than high school teachers, although the trend is toward the payment of equal salaries for equivalent preparation and experience.

Pupils. In 1938, 22 million children attended elementary schools. According to the 1930 census, ninety-five per cent of all children seven to thirteen years of age were in school. About eighty-six per cent of these were, on the average, in 1938, in attendance each day. Slightly more than half of all elementary school pupils live in the country or in towns of less than 2,500 inhabitants. One child in five is foreign-born or of foreign or mixed parentage. In nineteen states, the average annual expenditure per child in average daily attendance is approximately \$58. In 1936 it was revealed that out of every 1,000 children who had enrolled in Grade V, 831 pupils reached Grade VIII. J.A.H.

ELEMENTARY SCHOOL PRINCIPAL —See PRINCIPAL, SCHOOL.

ELIMINATION, PUPIL. The chronological age at which pupils leave school varies from state to state according to the legal school leaving age, which in 1938 was 14 in Louisiana, Georgia, and North Carolina, 15 in Virginia, 17 in Wyoming, North Dakota, South Dakota, Mississippi, and Maine, 18 in

ELIMINATION, PUPIL

Idaho, Nevada, Utah, Oklahoma, and Ohio, and 16 in all other states, with provision for working permits in exceptional cases for children below these ages.

The grade level at which most of the elimination occurs will, of course, depend upon the school's promotion practices as well as upon the age to which education is compulsory. Whether students remain in school beyond the minimum school leaving age depends upon such factors as the attractiveness of the curriculum, the economic need of the student, the child labor laws, and the availability of employment. In a study made of out-of-school youth in Maryland in 1937, nearly 11,000 youth between the ages of 16-24 gave reasons for having left school. Of these, 34 per cent cited lack of family funds; 16 per cent, the desire to earn their own money; 4 per cent, the necessity of working at home; 21 per cent, a lack of interest in school; 2 per cent, disciplinary trouble; 2 per cent, difficulty with subject matter; 3 per cent, poor health; 3 per cent, marriage; 13 per cent, a feeling of satisfactory completion when graduated from elementary school, high school, or college; and 2 per cent gave other reasons. A similar study in Pennsylvania revealed almost identical percentages. In states where children may leave school at a relatively low age, there is a good deal of withdrawal in the sixth, seventh, and eighth grades of the elementary school. While a large number of states have the same number of pupils in Grade VII as in Grade II, for the United States as a whole (in 1935-36), the percentage of elementary school children in Grade II was 12.5, while for Grade VII it was only 10.7. All states which showed a considerable difference between the number of students in the seventh grade and those in the primary grades were southern states. South Carolina, with only a seven year elementary school, should have had about 14 per cent of its elementary school enrollment in the seventh grade; actually, only 7.7 per cent of the children were found in Grade VII, showing that very considerable elimination was taking place below that grade. In the southern states, there is, furthermore, a decided difference between the mortality statistics of the white and the Negro students, the percentage of Negro students in high school being far less than

the percentage of white students receiving secondary education in the same state.

High school mortality is high throughout the United States. Of all pupils who enter high school only about half remain until graduation. In 1935-36 the highest mortality occurred during the first years, the sophomore enrollment being 82 per cent of that in the freshman year. In each of the other grades about 9 per cent of the students left, while in 1933 about 20 per cent of those who were graduated from high school entered college. Fewer than half of those who enter college are ever graduated from college, though the percentages differ greatly from college to college, the range being from about 25 per cent to 80 per cent.

From the Maryland and Pennsylvania reports cited above, it is seen that youth themselves attribute early school leaving predominantly to economic reasons, though a considerable proportion attribute blame directly to the curriculum which had been offered them. The failure of the curriculum to interest students reinforces the power of whatever economic reasons there may be to make them leave school. Many students who feel that they have to leave in order to earn some money may feel that necessity much less if their school experience is such as to make them desire to remain. The excessive amount of course failure in high schools tends to make many students look forward impatiently to the time when they will be permitted by law to leave school. Secondary education has not yet adapted its curriculum to a range of intelligence which is widening at the lower end as more and more of the nation's youth of high school age are required by law to attend school. That lack of ability is one reason why students do not complete the high school course is shown by the fact that a larger percentage of each decreasing I.Q. group fails to graduate. With most colleges being deliberately selective in terms of the ability of their applicants, it is not surprising that an exceedingly small number of students with an I.Q. of less than 100 ever enter college. Graduate schools are even more selective, reporting median I.Q.'s of 130 and 140.

Just as students of lower I.Q. drop out of school at a lower school level, so do a very much greater percentage of students of lower economic groups leave before their richer

classmates. There is a strikingly large difference between the number of college students from the upper three deciles of income and the number of college students drawn from families of the three lowest income deciles.

During a depression era, the holding power of high schools may be greater since the demand for young, inexperienced workers decreases. During such periods, too, employers tend to demand more schooling of their applicants for jobs, thus increasing the drive to stay in school. However, training for the vast majority of occupations is done on the job rather than in school, thereby eliminating one of the major stay-in-school drives for older boys and girls. The value of a long general education is not yet appreciated by a considerable proportion of the American population, and it is possible that such appreciation will not come until the curricula of both secondary schools and colleges are changed considerably. (See LIBERAL ARTS COLLEGE, PROMOTION, SECONDARY EDUCATION.)

ELIOT, CHARLES WILLIAM (1834-1926). Dr. Eliot was an American educator who touched his intellectual environment at many points. He was a prolific writer—Henry James's biography of Eliot lists fourteen pages of bibliography, giving the titles of his books, articles, and published addresses, most of them in the fields of education, the social sciences, and public affairs.

In the field of education, Eliot is important on the one hand as a leader of college and university reform, and on the other as a potent influence in the reorganization of secondary education.

College Reform—Electivism. During his long incumbency as president of Harvard (1869-1909), Eliot became identified with the movement to supplant a rigidly prescribed college curriculum with one incorporating the elective principle. When in 1869

he took up the cudgels for this reform, the American college curriculum provided practically no choice of studies. Harvard, fairly typical, allowed one Greek or Latin author to be studied rather than another, more or less mathematics, a little more time to science for some students, a little more to modern languages for others. Science, modally, was taught in a separate scientific school rather than as a corporate part of the American liberal arts curriculum. The courses in English were few and quite elementary; it was generally believed that a student could read English literature privately.

Eliot contended that the spirit of the American college must be "broadened, deepened, and invigorated". He believed that all branches must be represented in the college curriculum, and held that there was no real antagonism between the sciences and the humanities. (See SPENCER.)

To Eliot, it was variety of intellectual product and not uniformity that a democratic state had a right to expect from its colleges. As for individual students, they were entitled to the highest development of their own powers, which for some lay in the field of the sciences and for others in the field of the humanities. The American college should provide for both, incorporating the principle of electivism.

Reorganization of Secondary Education. Eliot's work has also been significant in the reorganization of the pattern of American education from the traditional eight-year elementary school, followed by the four-year secondary school, followed in turn by the four-year college.

Eliot joined with President Nicholas Murray Butler and other university administrators in the last decade of the nineteenth century in attacking egregious "waste of time" in the American system, owing to the late beginning of secondary education and the consequent late completion of the baccalaureate studies (three to five years later than in European countries).

In his Address before the National Education Association (1888), and in the Report of the Committee of Ten (*q.v.*) of this body (1892), Eliot drew national attention to this problem and to its solution, which, as he saw it, was to reorganize the American system of public education so that such genuinely sec-

ondary studies as foreign languages and mathematics beyond arithmetic should be made available at about the beginning of the seventh school year. With a retrospect of fifty years, there can be recognized in Eliot's thinking on this subject the embryo of the reorganization that later (c. 1910) fructified in the junior high school idea (*q.v.*).

EMOTIONAL ADJUSTMENT — See MENTAL HYGIENE.

EMOTIONAL CONFLICTS—See CONFLICTS (MENTAL AND EMOTIONAL.)

EMOTIONS. Emotions are spontaneous reactions which the organism makes to varying degrees of suddenness and intensity of the stimulating cause and to its own state of preparation for dealing with the situation. Emotions are complex responses made up of four component parts: (1) different degrees of intensity, as mild and strong; (2) different qualities known to the person having the emotion, as fear, joy; (3) different physiological changes in the organism, as increased blood, or glandular secretions; (4) different feeling tones, as pleasant and unpleasant. Emotions indicate an aroused or upset state of the organism causing the individual to do something which he hopes will restore a state of relative balance. The purpose of emotion then is to release energy for getting things done. If this aroused state results in a ready and effective response, little emotion is felt or shown and the normal physiological functioning of the organism is quickly restored. One of the purposes of education is to help prepare these ready and effective responses, to give children experiences from which they can glean methods of attack which solve rather than increase their problems. Obviously before children have learned to direct this released energy properly, they will do violent

things which increase their dissatisfaction, cause more tension, and frequently result in unreasonable behavior. The parent or teacher should help children find more adequate ways of meeting situations. The whole child cannot be educated until schools accept their responsibilities for training the emotional responses of the child.

Violent emotions are symptoms of maladjustment. The causes of this maladjustment should be found out and studied carefully, and some intelligent plan for its treatment should be made. Restraint only intensifies the emotions which the child may then direct either against himself in feelings of guilt, anxiety, and inferiority; or against others in resentment, vengeance, and destructive behavior. If, on the other hand, this released energy finds outlet in reasonably effective activity, with feelings of healthy self-respect, the child very likely will develop attitudes and skills which will insure his becoming a well-adjusted and happy individual. The primary tasks of education are to discover and treat the causes of maladjustments in children, and to help children develop criteria for judging the effectiveness of their activity and techniques for dealing adequately with situations as they arise.

EMULATION. Emulation refers to the attempt to equal or excel the achievements or personality traits of other persons.

Most people pattern certain phases of their behavior on models who seem to them worthy. This natural desire to emulate has been used from time immemorial by parents, teachers, and even nations as a principal means of character education. The boy of ancient Greece was exhorted to become as courageous as Achilles and as wise as Ulysses. Similarly the American boy may be expected to pattern his honesty after George Washington of cherry-tree fame, his learning after the log-cabin Lincoln reading law by firelight, his tenacity after the Horatio Alger hero reading the

ENDOCRINE GLANDS

temptation of financially profitable dishonor. Frequently, however, youngsters have their own particular heroes—the All-American football player, the home-run king, the movie star, the adventurous character of the comic strip—who set the pattern for mannerisms, dress, action, and play. The tendency to emulate is fostered actively by popular literature, the comic strips, motion pictures, and advertising. It is these influences, together with the changing trends in the news (the glorified gangster gives way to the G-man, the G-man to the Commando), that determine to a large extent the models who become the basis for emulation in young people. These influences are strong competition for the teacher or parent who wishes to make use of emulation in developing desirable habits and attitudes in children; too often “educational” emulation fails because the models it uses cannot always approximate the glamour of popular heroes of the moment.

The educational possibilities of emulation are subject to other common limitations: (1) There is the possibility of the child's personality maladjustments and of a waste of energy in the vain endeavor to emulate the achievements characteristic of those who are not worthy of emulation, or of those whose virtues and attainments, either supposed or actual, are so great that any attempt at imitation is doomed to failure. (2) There can be no emulation without the child's desire to imitate. Constant nagging is apt to lead to resentment and negativism rather than to the desired end. The youngster's self-respect does not permit to imitate someone of whom he disapproves (for example, the “sissy” who is always clean and neat) just to please the parent or the teacher.

When children themselves are to be used as models, it is advisable to spread the basis for emulation so that no one child bears all the burden of being the model—the “teacher's pet” is never liked and lives the unhappy life of a social outcast. Many children can be used as models, as when one is praised for his neatness and another for punctuality; even an entire group may be used as a model—“Second-year boys and girls always can be trusted to bring their books.”

To be successful, emulation must set goals

that are attainable, desirable (from the child's point of view), and socially acceptable.

ENDOCRINE GLANDS. The endocrine gland (glands of internal secretion, ductless glands) are a group of interrelated body organs. Each has a distinct function, but they are mutually interdependent. From the blood each gland takes materials which it makes over into specific hormones which are then returned to the blood. In general, these glands regulate body growth, nutrition, mental activity, and the reproductive functions. Included in this group are: (1) the pituitary, (2) the thyroid, (3) the parathyroids, (4) the thymus, (5) the islands of Langerhans, (6) the adrenals, (7) the gonads or sex glands. Many of the mental and emotional adjustment difficulties of school children are due to disturbances of glandular function. The extremes of glandular abnormality are usually diagnosed long before the child reaches school age. It is the border-line case or the neglected one that can be helped if the teacher is aware of the existence of such problems. A familiarity with the more common deviations from normal function may help the educator to understand a child's failures and to direct the pupil to the proper agencies for treatment.

Pituitary gland. The pituitary gland, about the size of an ordinary pea, is located within the skull and lies in a small socket in the bone which forms the rear of the nasal passages. It is composed of an anterior (front) lobe, a posterior (rear lobe), and an intermediate portion. The anterior lobe manufactures a complex group of secretions which control bodily growth, regulate the development and maturation of the sex glands, stimulate activity of the thyroid gland, regulate the function of the adrenal glands, stimulate the activity of the pancreas, and stimulate milk secretion in the breast.

Lack of anterior pituitary hormone during the growth period may cause stunting, and/or obesity with lack of sexual development.

ENDOCRINE GLANDS

Overactivity of this structure during the growth period, will result in gigantism: the general overgrowth of the skeleton may result in a stature of seven to eight feet. If overactivity begins after the bones have stopped growing (in adult life), acromegaly results: a widening of the bones, particularly of the face, hands, and feet, giving a leonine appearance. Lack of pituitary is being treated with extracts of the gland taken from animals. This treatment is still in the experimental stage. For overactivity, usually due to a tumor of the gland, removal is sometimes brilliantly successful.

The posterior lobe secretes a hormone which increases the contraction of involuntary muscles of the uterus and the intestinal tract.

Thyroid Gland. The normal thyroid weighs about an ounce and is composed of two lobes which straddle the upper part of the trachea (windpipe). The chief ingredient of its secretion is the hormone thyroxin, which is conspicuous for its iodine content and dependent for its manufacture on ingested iodine. The gland regulates the utilization and absorption of food (metabolism), the rate of respiration, the rate of circulation, growth, mental activity, and the function of the reproductive glands.

Deficient thyroid secretion (hypothyroidism) results in a slowing of all the body processes. Extreme hypothyroidism at birth results in cretinism, characterized by stunted growth and sluggish mentality. When acquired after growth is complete, hypothyroidism results in a tendency to gain weight, extreme sensitiveness to cold, slowing of the heart beat, slowing of the rate of respiration, lack of energy, mental slowness, and interference with the reproductive process.

Overactivity of the thyroid (hyperthyroidism) speeds up all of the body processes: the pulse is rapid; there is increase in the rate of food digestion; increase in appetite is accompanied by loss of weight; there is an increase in temperature, restlessness, and nervous irritability. In extreme cases, the eyes become very prominent, often to the point of protrusion. This condition may or may not be accompanied by a visible enlargement of the gland itself.

In deficiency, administration of thyroxin or of tablets made from the whole dried gland produce results that are markedly successful.

In overactivity, removal of part or all of the gland has proved a very satisfactory method of treatment.

Parathyroids. The chief function of the parathyroids (four tiny glands situated on the under surface of the thyroids) is to regulate the utilization of calcium by the body and to control the proper distribution of lime salts to the tissues. A lack of this hormone produces nervous irritability with muscular cramps, muscle spasms, and even convulsions accompanied by degenerative changes in the hair and nails. An excess produces a disturbance of bony structures because of too great a withdrawal of lime salts from the bones into the blood.

A lack of secretion may be overcome by the administration of an extract of the glands.

Thymus. The thymus gland is situated in the upper part of the chest just behind the breast bone. It is prominent during the first years of life and tends to disappear after adolescence. It has been thought to aid in growth and to be an important factor in the development of the reproductive organs.

Islands of Langerhans in Pancreas. The pancreas is in the abdominal cavity, a little below and behind the stomach. Scattered through its substance, are groups of highly specialized tissue known as the islands of Langerhans. They manufacture a hormone, insulin, which enables the body tissues to utilize the carbohydrates which are ingested; it also enhances the body's ability to convert sugar into glycogen and to store it in the liver and muscle tissue for use as the need arises.

A lack of insulin, resulting apparently from a degeneration of these glandular tissues, is the cause of diabetes: a complete inability to utilize and store ingested carbohydrates with a consequent loss of sugar from the tissues and a concentration in the blood and urine. This waste of carbohydrate results in extreme hunger and thirst, with loss of weight and strength. In more severe cases, coma and even death may result.

Lack of insulin may be corrected by the injection of the hormone isolated from the pancreatic tissue of sheep. (Since insulin is destroyed by the juices of the stomach, it cannot be taken by mouth.)

Adrenal Glands. The adrenals are small glands which fit over the top of the kidneys.

They are composed of two portions: an outer *cortex* and an inner *medulla*, each producing a specific hormone.

The cortical hormone, cortin, is necessary for the proper utilization of oxygen by the body; it is also important in maintenance of adequate circulation of the blood. It is also intimately connected with the function of the sex glands. Disease of the cortex of the adrenals causes death unless the hormone is supplied. Tumors of the cortex cause profound changes in sex characteristics.

The medullary hormone is adrenalin (sometimes called epinephrin). Adrenalin is an activator and stimulator of practically all body activities. Conditions that produce fear and the need for flight, or anger and the need for action stimulate increased adrenalin, which in turn increases the pulse rate and releases tissue reserve energy. The extract of the adrenal gland is used to raise blood pressure in cases of collapse, to relieve nasal congestion, and to stop bleeding. It is one of the indispensable drugs.

Reproductive Glands. These glands (the gonads) comprise the ovaries in the female and the testes or testicles in the male. They produce the ova of the female and the sperm of the male, respectively; in addition they produce several internal secretions which affect the distinguishing characteristics of the two sexes and the various sex functions. The internal secretions of the ovary seems to be an activator of general body activity. Removal of the gonads before maturity prevents typical sex development. In the male, height is increased, the voice remains high pitched, the face remains hairless, fat is deposited in feminine fashion, and the sex organs remain infantile. In the female, the appearance becomes masculine and menstruation does not take place. After maturity, removal of the gonads or decrease in function causes minor changes in appearance and results in diminished function of the reproductive mechanism. A relative deficiency begins in all persons at middle life. Several laboratory produced hormones are used in cases of deficiency. (See also HEALTH.)

ENDOWMENT. When used as a financial term, *endowment* refers to a sum of money the principal of which is to be maintained intact, and only the income of which can be used. Endowment fund is the principal amount; endowment income is the income derived from the principal or endowment fund. Endowed college or university refers to one not supported at public expense and whose support comes mainly or largely from endowment funds, though some such endowed schools receive some income from public funds. The income on an educational endowment is devoted to educational purposes.

The first endowed educational institution is said to be Plato's house in 347 B.C. The history of endowments in England shows more endowed schools below collegiate rank than of collegiate rank. Also in England the separate college within the university, rather than the university itself, has been endowed.

In 1880 more than half the income for institutions of higher education in America came from endowment funds. For 1935-36 the fraction was reduced to less than one-eighth of the total income. In 1937-38, 2.6% of the total general income of publicly controlled institutions of higher education and 25% of the income of privately controlled institutions of higher education came from endowment funds. ENGINEERING EDUCATION. It was not until the 18th century that the civil engineer was recognized as the designer of works especially for civilian use, most earlier engineering achievements having been the pro-

ducts of military engineers. Up to 1850 Paris was the leading influence on engineering education. Great Britain had only three small centers, each with a single professor, but in time it developed the technical institute to a high degree of efficiency. Later followed the German technical *Hochschule* or *Technicums* of which there are many today.

Engineering education was started in the early years of the American republic. West Point was instructing a corps of engineering cadets during the War of 1812, and it emerged as a school of advanced character in 1817. Instruction followed in a general way the *École Polytechnique* of Paris. Rensselaer Polytechnic Institute, established in 1823 as Rensselaer School, developed into the first professional school of civil engineering in the English speaking world. Amos Eton was the organizer, and his successor, B. Franklin Greene, reorganized the curriculum and stamped it with a character which influenced other institutions. Dartmouth College taught civil engineering in 1845 and established Chandler Scientific School in 1851 "to be a school of industrial vocations." Early venturers into this new field were the University of Georgia, the University of North Carolina, Harvard, Yale, Union College, Brown University, the University of Missouri, and others. The University of Michigan in 1852 was the first of the state institutions to give instruction in engineering.

The Morrill or Land Grant Act of 1862 gave a significant incentive to the states to create or designate institutions "for the applications of science to the common purposes of life." The Massachusetts Institute of Technology and many of the other Land Grant Colleges were organized soon after the Civil War ended. Their influence on the development of engineering education from its early "mechanic arts" to its present form has been momentous. Columbia University was the first to establish a school of mines; mechanical and electrical engineering were included later, and many other curricula followed. By 1870 there had come a definite development of the laboratory as an instrument of instruction, and later, of research and graduate study. At that time the laboratory was not part of the instruction in European schools, but was later adopted by technical institutes and engineering colleges abroad.

Trade, Technical, and Engineering Education. The manufacturing and engineering industries require large numbers of skilled workmen. Trade and vocational schools have been established to meet this need. Here boys with manual aptitude are prepared for a variety of occupations, such as plumbing, welding, pattern making, and the trade of mechanics, but the distribution of these schools is neither adequate nor equitable. The system of apprentice training is still used to train skilled workmen, but it is not employed as generally as it was before the trade school was organized.

The technical institute gives a brief, more intensive, more directly practical course than the higher professional schools for engineers. In 1928-29 the National Industrial Conference Board estimated that "upwards of 90,000 recruits for technical and supervisory positions per annum" were needed by American industry. Fewer than 1,500 of these men were furnished each year by the technical institutes, while some 9,000 more were graduated from the engineering schools, a number which had increased in 1942 to about 13,500.

The curricula of the engineering schools provide both general academic and professional education. Approximately one-half of the subject matter is general or academic and dominates the first two years. About one-sixth is cultural or humanistic in nature, including such subjects as English, economics, history, psychology, and other courses which are available as electives. The basic sciences comprise perhaps one-third of the course and include mathematics, physics, chemistry, mechanics, bacteriology, hydraulics, electricity, magnetism, thermodynamics, geology, and minerology. Professional engineering is confined largely to the last two years and includes instruction in the theory of structures; the techniques of surveying; the design, construction, and operation of bridges, buildings, mines, railways, waterways, highways, airways, engines, generators, motors, and gas, water, sewage, and chemical works.

The major curricula are in civil, electrical, mechanical, mining, and chemical engineering. Later additions include aeronautical, architectural, ceramic, metallurgical, petroleum engineering, and others. A recent trend is to reduce specialized instruction and to add or substitute subjects in management,

psychology, and the social sciences.

Methods of instruction in engineering subject include class recitations, lectures, laboratory, and field work. A given course may utilize all these methods.

By October 24, 1940, a list of 542 engineering curricula in 125 engineering colleges had been surveyed and accredited by the *Engineers' Council of Professional Development*, an organization representing eight national engineering societies. The diplomas of these curricula are recognized by State Boards of Engineering Examiners for professional or licensed engineers. Other committees of the Engineers' Council are: 1. Student Selection and Guidance, 2. Professional Training, and 3. Professional Recognition. A special committee is formulating "Canons of Ethics for Engineers."

Cooperative Instruction.

A number of engineering schools organize their instruction so that a student is in residence for a period of from one to three months, after which he takes a job in industry and is replaced by a fellow student who returns to the campus. Thus one-half of the students are in industrial work, while the other half are receiving class instruction. Some institutions start this program in the freshman year; others postpone it until the sophomore year. While the cooperative plan lengthens the time required for graduation to a period of at least five years, it does enable the student to earn part of his expenses while learning, and gives him a working knowledge of industry, labor, and management. (See COOPERATIVE EDUCATION.)

Qualifications Desired of Engineering Students.

The minimum requirements for admission to a four year engineering school which grants a diploma, are graduation from an acceptable four year high school course with: (1) at least one and a half years of algebra, a year of plane geometry, and a half year of either solid geometry or plane trigonometry; and (2) work in English, history, and science. While the particular requirements may vary, the total is usually 15 high school units.

The fact that, on the average, less than 40 per cent of those entering engineering colleges are graduated has led to a study of aptitudes and scholastic fitness. Some institutions set minimum averages in all high

school subjects; others require students to pass the Regents Examinations of New York State, the College Entrance Board Examinations, or a variety of tests such as the Scholastic Aptitude Test of the American Council on Education, tests in special subjects, aptitude or achievement tests. (See PROFESSIONAL APTITUDE TESTS.) The results are used in counseling applicants or those who are failing. Instead of dropping the student from college after having accepted him as a fit person to pursue a higher education, the more humane method now followed is to assist him in finding the academic field for which he is best fitted.

The social importance of engineering and the impact of new inventions and labor saving machinery on occupations is leading to a demand that the engineering educators take more responsibility for social controls, retraining for new jobs, and for occupational security. R.L.S.

ENGLAND AND WALES, EDUCATION IN. The system of education in England and Wales, in organization and administration, presents many aspects which may prove unfamiliar to American eyes. The three most distinctive features, as outlined in a recent publication of the British Board of Education, are as follows:

ENGLAND AND WALES, EDUCATION IN

1. The decentralization of responsibility and control

2. The prominent part played by voluntary agencies

3. The freedom of teachers from official control on questions relating to curricula, syllabi of instruction, and methods of teaching.

The central and local authorities consult and cooperate, either by direct contact or through the Board of Education liaison officers, His Majesty's Inspectors of Schools, who generally reside in the areas of the various local education authorities. The Local Education Authority is not the same as the American type of board of education. The L.E.A. is the local government (council) and is divided into committees of which the education committee is one. Both central and local authorities are bound by acts of Parliament. By these Acts definite duties are placed on the Board expressed either as Statutory Regulations or in Circulars addressed to local education authorities. The latter, however, which are popularly elected, enjoy real autonomy. The prominent part played by voluntary agencies in British education is due to the fact that in the first instance educational provision was made by religious bodies, voluntary societies, and public spirited individuals. Opponents of the system say that the agencies have created a vested interest, while those who favor it say that it established a tradition of voluntary effort, which is the most valuable feature of the state system today. For good or evil, it does play a vital part in the educational system of England, and a full appreciation of this fact is necessary in order to understand English education.

The teachers are the servants of local authorities or of the managers of schools or of governing bodies. Head teachers enjoy wide powers in the organization of their own schools, plan the curricula in consultation with their staff, order their own textbooks, and both they and the other teachers have wide freedom in methods of teaching.

The Board of Education and the local education authorities, however, advise teachers and can make their views known through the medium of reports by their respective offices. The Board also collates results of interesting experiments, issues pamphlets on topics, and

periodically publishes a "Handbook of Suggestions for the Consideration of Teachers in Public Elementary Schools".

The Board of Education has also a Consultative Committee, composed of distinguished administrators and educators, to whom the President periodically refers matters for investigation and report. Recent valuable reports of this committee, which have influenced educational organization in the country, are *Education of the Adolescent*; *The Primary School*; *The Infant and Nursery School*, and *Secondary Education*. These reports summarize the opinions of responsible British educators on these subjects.

Administration. The central authority is known as the Board of Education, with a political head known as the President, who is also a member of the Cabinet. Serving with him is a Parliamentary Secretary, who is also a member of the Government and of Parliament. The Board functions through a permanent staff of civil servants stationed in London, and Inspectors who work in the field.

The universities lie outside the jurisdiction of the Board; so also do approved schools for delinquents (Home Office), education for agriculture (Board of Agriculture), and Ministry of Labour Instruction Centres. In the words of a Board Publication: "The Board does not provide, own or directly control any educational institution; it does not prescribe, compile or publish textbooks for use in educational institutions; nor does it employ or pay any teachers. Public educational institutes are locally provided, maintained and controlled with the financial assistance and advice of the Central Authority."

Local Education Authorities. Altogether in England and Wales there are 315 Local Education Authorities, composed as follows: 63 County Councils, 83 County Borough Councils, 150 Borough Councils, 19 Urban District Councils. All County Borough Councils are education authorities, but only those Borough and Urban District Councils are education authorities whose boroughs and urban districts respectively had a population of over 10,000 and 20,000 in 1901. Further only County and County Borough Councils are education authorities for both secondary and elementary education. These Councils, which are popularly elected, are the authori-

ties for almost all forms of local government as well as education; consequently they administer education through an education committee, generally composed of some members of the Council plus co-opted educationalists, some of whom must be women. The Local Education Authority has its own officers, the chief of whom is known as the Chief Education Officer, Director of Education, or Secretary to the Education Committee. It also employs other technical officers, generally known as organizers or inspectors of schools. Authorities for elementary education alone are responsible for seeing that all children between the ages of five and fourteen or fifteen years receive efficient elementary education, while those responsible for both forms, are responsible also for those whose education will go beyond that age in Secondary Schools, Technical Schools, Schools of Art, Schools of Commerce, Trade Schools, Teachers Training Colleges, Adult Education classes, etc. The County Councils are responsible for the higher education in the areas of the Borough and Urban Districts, situated within the county, and work in close cooperation with them. Attendance at elementary schools is compulsory from five up to the end of the term in which a child attains the age of 14 years.

Voluntary Bodies. Voluntary agencies as well as Local Education Authorities are responsible for the full or part provision of almost every grade of education in the area. They provide nursery schools, special schools, elementary schools, secondary schools, training colleges for teachers, and adult education classes. These may be wholly maintained, or just financially assisted by the L.E.A.: many receive a grant direct from the Board of Education, or may be entirely responsible for their own finances. There are, in addition, in Britain a large number of private schools, some of which are wrongly termed "public schools," which receive no aid from either authority, but many of which, at their own request, are inspected by the Board's Inspectors.

Financial Arrangements. Practically the whole of the expenditure on education is met jointly by the Board of Education and the Local Education Authorities, the former from national funds voted by Parliament and the latter from local "rates," a kind of

property tax. The Board of Education disburses its funds in the form of a percentage grant on approved expenditure of Local Education Authorities; the grant is made on the basis of the following formula:

Elementary Education:

60 per cent of Teachers' Salaries,

50 per cent of Special Services, which include nursery schools, school medical service, provision of meals, schools for defective children, organization of physical education play centres, and maintenance allowances. Under the Education Act of 1936 (now, 1942, in abeyance) a 50 per cent grant was paid on expenditure in non-provided schools (voluntary body schools), building, and all costs incurred on Hadow reorganization.

40 per cent of cost of conveyance of children.

20 per cent of remaining net expenditure.

In addition, the Board makes a per capita grant of 36/- for each unit of average attendance in elementary schools. But for the purpose of equalizing distribution of grant, as between poor and rich authorities, from the sum total of the above is deducted the product of a 7d. rate in the area.

Higher Education:

50 per cent grant on all expenditure connected with higher education (Secondary, Technical Schools and Colleges, Training Colleges, etc.).

Other Forms:

The Board also makes grants amounting to an approximate annual total of £2,206,000 to bodies other than Local Education Authorities. These include the following: training of teachers in voluntary training colleges or universities; voluntary schools for defective children; boarding schools such as Dr. Barnados Homes; play centres and nursery schools; secondary schools receiving direct grants from the Board; tutorial adult classes; grants to individual students (state scholarships at universities, training college students, Royal College of Art and Imperial College of Science), and grants to voluntary organizations for the provision of facilities for physical training and recreation. The distribution for 1937 and the total for 1939 is set out below.

ENGLAND AND WALES, EDUCATION IN

	Exchequer	Rates
Universities	£ 1,914,103	£ 509,959
Agricultural	290,614	156,131
Elementary	34,697,331	35,211,720
Higher	10,811,230	9,756,136
Miscellaneous	433,267	
Teachers' Pensions	7,133,384	
Administration	662,625	
Total	55,942,554	
Less Receipts		
Teachers	2,821,087	
Employers	2,818,594	
Other	51,284	
Total Receipts	5,690,966	
Net Total (1937)	£50,251,588	£45,633,946

Elementary Schools. Compulsory attendance age—five to end of term in which a child attains the age of fourteen. In 1936 the upper age limit was raised to fifteen, but the enforcement of this provision was postponed to the end of the war. Children under five may attend nursery schools or nursery classes which are increasing in numbers. The duty of securing compulsory attendance is laid on the L.E.A., who must prosecute any parent who neglects to cause the child to receive efficient elementary instruction. All elementary education is free. There are two types of elementary schools: those provided by the authority (Provided or Council Schools), and those built by voluntary agencies (Voluntary or Non-Provided Schools), mainly the Church of England and the Roman Catholic Church. The L.E.A. is responsible for maintaining all public elementary schools, whether Provided or Non-Provided; maintenance of Non-Provided Schools includes salaries of teachers, furniture and equipment, books, apparatus and stationery, heating, lighting and cleaning, and making good fair wear and tear. Teachers in Provided Schools are appointed by the L.E.A., and in Non-Provided Schools by the managers, subject to the approval of the L.E.A., who can withhold approval on educational grounds only. All Provided Schools can give religious instruction (and all do), which must not be that of any particular religious denomination. Religious instruction in Non-Provided Schools conforms to that of the body providing the school. Pupils at both types of schools are protected by a "Conscience Clause," which provides for the exemption of pupils and students from religious

instruction in schools and training colleges maintained by or in receipt of financial aid from public authorities. The L.E.A. is responsible for all secular instruction in both Provided and Non-Provided Schools.

Formerly there were two types of elementary schools: one, the Infants', for children from 5 up to 7 or 8 years, and one for children of all ages from 7 or 8 to 14 and 15. Since 1926, elementary education in Britain has undergone a process of reorganization, into Infant—5 to 7 or 8; Junior—7 or 8 to 11; and Senior or Modern Schools—11 up to 14 or 15 or even 16. Hundreds of well equipped new Modern Schools were built, which differed little, if at all, apart from equipment and organization, from the "Secondary" Schools. During the last 20 years many nursery schools were also built by the L.E.A.

The curriculum in the elementary schools always includes the following subjects: English language, handwriting, arithmetic, drawing, nature study, geography, history, music, hygiene, physical training, handicrafts, and domestic subjects. To these are frequently added general science, a modern language, commercial subjects, and other subjects. The Modern Schools generally have a "bias" toward the occupation the child is likely to enter: commercial, industrial, domestic, or rural.

Secondary Schools. These provide a general education, as distinct from vocational, for students from the age of 11 to 17 or 18, and are of three types: those wholly maintained by the L.E.A., those aided by the L.E.A., and those which receive a direct grant from the Board of Education. Outside these lie the "Public" schools and other private schools, both day and boarding. Many day schools both private and secondary (generally the Grammar Schools) claim the title "Public", but these in reality are certain of the non-local boarding schools, such as Eton, Harrow, Winchester, Rugby, Oundle, etc. In schools in which the L.E.A.'s aid, they are represented on the Governing Body. Schools in receipt of grant are inspected by the Board of Education.

All publicly aided secondary schools must charge fees, which vary considerably from area to area. All local education authorities conduct what is known as a Special Place's

Examination for entrance to secondary schools at the age of 11 or 12. A large number have a 100 per cent Special Place's Examination: *special place* children pay fees in accordance with the financial position of the parents. The scales are so generous that in many cities a large number pay no fees.

There are boys' schools, girls' schools, and coeducational schools. In the cities the majority are one-sex schools.

To comply with certain requirements laid down by the Board of Education, the curricula generally include the following subjects: English language and literature, at least one foreign language, geography, history, mathematics, science, art, music, manual instruction, domestic subjects, physical exercises, and organized games. In addition, there are many "optional" subjects, with a leaning towards commerce and industry. About the age of 16, after five years' instruction, nearly all pupils take the "School Leaving Certificate Examination." The majority leave school at this stage, but many stay on till 18, when they take the "Higher School Certificate Examination." Both are conducted by University Examining Bodies, approved by the Board of Education. It is now generally expected that a student will have passed the "Higher School Certificate" before admission to a university.

Teachers in the secondary schools are not, like their colleagues in the elementary schools, expected to possess certain prescribed qualifications laid down by the Board. Nearly all are university graduates, or possess special qualifications for their particular subjects. Unlike the high schools in America, these schools seldom exceed 500-600 in enrollment.

Full Time Junior Technical Schools, Trade Schools, etc. These schools generally prepare their pupils mainly for industry and commerce. Pupils in these schools are generally admitted at the age of 13 and under to instruction for two or three years. They include Technical, Trade, Commercial, Art, Nautical Training, and Housewifery Schools.

Further Education. There is a wide range and variety of education provided quite apart from that of university education. This extends from the part-time education of the evening institutes to the senior full-time courses of the larger Technical, Commercial, and Art Colleges. The part-time courses are

generally held in the evening, though there are many daytime classes, and cover almost every range of subject from the preliminary technical, preliminary commercial, rural and domestic of the junior part-time courses, to that of the advanced courses of the engineering, building, chemical, and printing trades. Though these courses are mainly vocational, courses of a general character are also provided. The full-time courses are a preparation for employment in building, engineering, commerce, art, domestic crafts, etc., and in many cases National Diplomas are issued at the end of the course. Students attending part-time and full-time take a wide variety of examinations conducted by such bodies as the City and Guilds of London Institute, Institute of Bankers, and Institute of Chartered Accountants. The Board of Education has also established a scheme in cooperation with Professional Institutions concerned for the award of National Certificates in mechanical engineering, electrical engineering, chemistry, naval architecture, building, textiles, and commerce.

Adult Education. This refers to the provision of liberal, practical, and recreational instruction for persons of mature age as distinct from the vocational and general education referred to above as "Further Education". This type of education is provided by the following organizations:

- Universities and University Colleges, in
- Voluntary Organizations,
- Local Education Authorities,
- Collegiate and Other Institutions,
- Charitable Trusts,

Universities and University Colleges, in cooperation with the Workers' Educational Association, provide extra-murally: (a) three years' Tutorial Classes equivalent to the standards for an honours degree, and (b) less advanced Sessional Courses. These joint committees also employ full-time tutors on this work.

As an indication of the type of work carried out, the Workers' Educational Association organizes a large number of one-year and terminal courses, and organized rural schemes for Adult Education. The Federation of Women's Institutes has 5,700 institutes with a membership of 327,800, and organizes classes on such subjects as literature, history,

music, drama, craftwork, hygiene, and food production and preservation.

The Local Education Authorities organize thousands of classes for adults, mainly in domestic subjects, handicrafts, hygiene, music, physical training, elocution, literature, and science.

The Special Services. Safeguarding the health and general welfare of children is part of the educational system in Britain. The Board of Education has a health department which supervises, while the actual work is carried out by the Local Education Authorities through their medical and nursing staffs. Children are examined medically, not less than three times during their school life: when they enter school, and at the ages of 8 and 12. Any defects discovered are called to the attention of the parent and, if necessary, treatment has to be found by the Local Education Authority for certain defects of eyes and teeth, tonsils and adenoids, etc. This treatment has been greatly extended during recent years, and now generally includes treatment of crippling defects, heart disease, and rheumatism.

Local Education Authorities provide education for defective children in special schools for the blind, deaf, physically defective, mentally defective, and the epileptic. For the blind and deaf, attendance is compulsory from the ages of 5 to 16, and for the other defectives from 7 to 16. Schools can be provided by education authorities, health authorities, or voluntary bodies.

Local Education Authorities may provide meals, free if necessary, for children who, through lack of food, are unable to profit from elementary instruction. Since the war this provision has been greatly extended, and it is hoped soon that all children will be able to secure meals in schools. In addition to meals, milk is also provided daily at a cheap rate, or free, if necessary.

Nursery schools are for children of 2 to 5 years of age. Attendance is optional.

Training, Salary and Superannuation of Teachers. It is not now possible (with few exceptions) for a teacher in the public elementary schools to be recognized by the Board of Education without having undergone an approved course of training. Teachers in secondary schools are generally graduates of such an approved course of training,

and more are taking a professional course of training than formerly. There is no prescribed course of training for teachers in Technical schools.

This training is given in Training Colleges provided either by Local Education Authorities or Voluntary Bodies, and in the Training Departments of the Universities. Elementary school teachers, after having completed their education in a Secondary School, proceed at the age of 18 to a Training College for two years. There are 70 Training Colleges, 22 provided by Local Education Authorities and 36, by religious bodies. The remaining 12 are undenominational, and are maintained by voluntary bodies.

Training at a university training department consists in spending a fourth year at a university after having completed a degree course of three years. There are 22 such training departments.

There are also 11 special training colleges for the training of teachers of domestic subjects, and at least four colleges for the training of teachers of physical education.

At the end of their training, teachers are examined by regional joint boards composed of representatives of universities, training colleges, and other bodies interested in the training of teachers. Students at the university training departments are examined by the universities. A student's teaching ability is assessed by an Inspector of the Board in consultation with the training college or department. Recognition by the Board depends on the successful passing of the examination plus twelve months of satisfactory teaching service.

Salaries are paid in accordance with the national scales (Burnham Scales), arrived at by joint committees of teachers and Local Authorities and approved by the Board of Education.

The State Teachers Superannuation Scheme is as follows: teachers contribute 5 per cent and employers 5 per cent. At the age of 60, or previously if a health breakdown has occurred a teacher is entitled to a life pension of $1/80$ and a lump sum of $1/30$ of the average yearly salary for the last five years of service for each completed year of service up to a maximum of 40 years. Thus a teacher earning \$2,100 a year would, after 40 years of service, receive a life pension of

ENGLAND AND WALES, EDUCATION IN

\$1,050 plus a lump sum on retirement of \$2,800. There is also a death gratuity, if death occurs before retiring age, of a year's salary or 1/30 of the annual salary for the last five years for each year of service, whichever is larger.

Universities. The universities of England and Wales which have the power of conferring degrees are the following: Birmingham, Bristol, Cambridge, Durham, Leeds, Liverpool, London, Manchester, Oxford, Reading, Sheffield, and Wales. There are also the university colleges of Exeter, Nottingham, Southampton, from which students generally take the degrees of London University. Oxford, Cambridge, Wales, Durham, and London comprise groups of a number of autonomous colleges.

To aid poor students to proceed to the universities, there are many financial sources available. The Board of Education grants state scholarships; local authorities give scholarships, grants, and loans; and the colleges themselves are in many instances well endowed. There are also many private trusts and benefactors, so that a total of between 40 per cent and 50 per cent of the students at the universities are assisted from these many sources.

The universities are completely independent of both state and local authority control, despite the fact that they receive annually the sum of more than twelve million dollars (pre-war rate of exchange) from the state and the L.E.A.'s. To ensure their independence, the money from the state is paid direct through a University Grants Committee, composed of representatives of the universities, with an office and staff of its own. There is no inspection and no enquiries are made as to how the money is spent, though the Committee submits a report periodically to the Exchequer.

Statistics.

Population of England and Wales	41,215,000
<i>Public Elementary Schools</i>	
Total Number of Pupils	5,035,000
Pupils in Council Schools	3,513,000
Pupils in Voluntary Schools	1,522,000
Total Number of Teachers in Public Elementary Schools	167,000
Number of Certificate Teachers in Public Elementary Schools	132,000

Secondary Schools

Total Number of Pupils in Schools Recognized as Efficient (including Preparatory Schools)	569,000
Pupils in Grant-aided Secondary Schools	470,000
Pupils in Other Recognized Schools (including Preparatory Schools) ..	99,000
Total Number of Full-time Teachers in Grant-aided Schools	25,000
Number of Full-time Graduate Teachers in Grant-aided Schools	20,000

Vocational Schools and Further Education

Number of Students	
In Junior Full-time Courses	31,000
In Senior and Other Full-time Courses	19,000
In Part-time Day Classes	59,000
In Part-time Evening Classes	1,200,000

Adult Education

Number of Students	58,000
(This figure excludes students in certain Adult Education Courses recognized under the Regulations for Further Education—such students are included in the 1,200,000 figure given above.)	

Training Colleges and Departments

Number of Students	
In Training Colleges	9,600
In University Training Departments .	4,800
In Domestic Science Training Colleges	1,300

Universities

Number of Full-time students	49,000
------------------------------------	--------

Proposals for Reconstruction. Considerable attention has been given to the reconstruction of the educational system after World War II began, and plans have been published by official and voluntary agencies. The general trend is in the direction of increased educational opportunities with increased attention to health and security of children, increased provision for nursery schools, and the raising of the age of compulsory attendance to 15 or 16, followed by compulsory part-time education in continuation schools. It is planned to provide some form of secondary education for all from the age of eleven on, either in schools of different types or in "multilateral schools" corresponding to the American comprehensive high schools. Access to the universities is to be facilitated and increased facilities for adult education are to be provided. Various proposals have also been made for the establishment of youth organizations either on a voluntary or on a compulsory basis. The improvement of teacher preparation is recognized as important. Some reorganization of the administrative areas to make possible the provision of equality of educational opportunities is being considered. Other problems which

have to be met include the status of "public schools," the place of private schools, the future of non-provided elementary schools, and the status of religious instruction.

ENGLISH, TEACHING OF. In the broad sense, the teaching of English embraces all instruction conducted in the English language. Language patterns are determined by the language environment. For this reason the problem of the improvement of reading and of expression in language has been attacked most successfully in those schools which have furnished specific guidance wherever language situations are encountered.

English as a specialized branch of instruction has come to embrace numerous functions unknown in an earlier period when it included only classic literature and mechanical language skills. Today the development of reading competence is recognized as a responsibility of the high school and college as well as the lower elementary school. The ability to read the newspaper with understanding and critical discrimination is now widely regarded as a major objective for English in a time when newspapers rank first among the materials read by adults and play so vital a part in the determination of public opinion. Teachers of English in leading secondary schools no longer restrict their reading lists to the classics, but encourage wide reading in books and magazines of all kinds, with the purpose of improving the quality and extending the range of young people's everyday reading. Radio drama and photoplay take their place with the best in the history of the English and American theatre as subjects of analysis and enjoyment. In the field of language expression the modern teacher of English aims at clarity, force, and precision in the forms of communication most frequently encountered in the lives of youth

today — the conversation; the interview; group discussion; the informal floor talk; the friendly letter; the business letter; the personal journal; and imaginative writing for recreation, self-expression, or persuasion.

The new point of view places emphasis upon the language and reading needs of the learner. Literature is read not so much for factual knowledge of authors' biographies or the contents and structure of famous literary units as for the increased understanding of human behavior and grasp of human values which great writing affords. Reading becomes a key to the whole world of language-in-print which even to the non-academically minded yields new horizons, extends the experience range immeasurably, and promotes effectiveness in social living. For limited book lists and prescribed book reports, programs of free reading are substituted.

Classroom practice has been correspondingly modified. Discussions center about problems, with illustrations taken from the wide range of books and characters represented by the reading of individual students; or about literary types, with poetic or fictional or stylistic values discovered through exploration of the works of many writers, in many nations and many periods. Reading becomes a means of seeing individuals in their reactions to other individuals or to the stresses of society as a whole; or in other moods it provides essential information or on occasion wholesome escape from anxiety or fatigue. As a result, the teacher of English seeks to become familiar with a vast diversity of reading matter appropriate to all types of adolescent readers.

Mere volume of reading, however, is not in itself a sufficient objective. The totality of the reading program should eventuate in a broader understanding of and a sturdier devotion to the values upon which the democratic society is founded. English classes are increasingly studying literary materials from a variety of sources from the point of view of their significance in the long struggle of mankind for greater freedom, equality of opportunity, and security against want and ignorance. The social issues are commonly examined largely with relation to their impact upon individual lives.

Far-reaching changes have occurred also in the field of the teaching of language expres-

sion. Research studies overwhelmingly demonstrate the futility of instruction in formal grammar (isolated exercises in syntax and inflection) as a means of improving effectiveness or correctness in speaking and writing. Standards of conventional usage are now taught by leading teachers in direct relation to the language needs of students. Textbooks in English are eliminating many formal rules derived from the grammar of classical languages and are deriving their data from the facts of the living language as reported by competent linguists. Emphasis is placed upon the communication of meaning through the comprehensive exploration of verbal, social, and psychological contexts. The enriched program in English instruction now embraces a highly varied combination of social situations involving written or spoken language. Teacher-assigned topics for composition are giving way to purposeful, real-life communication in the typical English classroom. Corrective work is becoming a part of the service function of the English teacher in connection with the genuine expressional needs of youth.

Finally, the sharp separation between instruction in reading and instruction in expression is disappearing. The semantic approach (*q.v.*) has united the two in its emphasis on language for meaning in the two-way process of reading and writing, speaking and listening. And the new plan of curriculum organization around student needs and purposes has drawn both phases of language communication into the process of social living and personal fulfillment through language. ENRICHED CURRICULUM—See CURRICULUM, ENRICHMENT OF.

ENVIRONMENT, SCALES FOR MEASURING. Even to measure roughly an individual's psychological environment—i.e., the sum-total of stimuli to which he reacts—is obviously a task so complex as to be impossible. Frequently, however, it is desirable to obtain some measure of certain environmental factors likely to exert an important influence on a child's development, such factors as the socio-economic status of his family or the general cultural level of the neighborhood. There are available for this purpose several scales and schedules purporting to measure these and other important environmental variables in a standardized way. The measurement consists of giving ratings of a certain degree of goodness or badness, as indicated by the scale, to specified conditions and objects which are found in that particular home or neighborhood or are lacking. Naturally, there is often great disagreement as to what constitutes goodness and badness, and as to whether the piling up of a high score owing to an abundance of good material conditions actually means a continuing increase in the favorableness of that environment for child growth and adjustment.

When the scale is simply defined in terms of a more specific criterion, for example socio-economic status, without the connotation that high status means a favorable environment, then the scale itself can be used to test whether scores on the scale are correlated with high scores on adjustment, achievement, intelligence, etc. The particular environment-

al variable selected for rating may also be one that it is deemed necessary to keep constant while the interrelationship of other factors is studied.

In any event, there is not only the question of the validity of the scale, but also the degree to which the ratings can be made reliably. Such measures have been developed by Burdick, McCormick, Sims, Chapin, Van Alstyne, and others. The early Whittier Scale for Grading Neighborhood Conditions (1919) and the more recent Minnesota Home Status Index (1936) for the measurement of urban home environment illustrate the general type of content to be found in these measures. In using the Whittier Scale an observer rates a neighborhood on each of the following characteristics: (1) neatness, sanitation, and improvements; (2) recreational facilities; (3) institutions and establishments; (4) social status of residents; (5) average quality of homes. In using the Minnesota Index an interviewer asks numerous specific questions bearing upon the home's facilities for children, its sociality, and cultural, economic, occupational, and educational status. On the basis of the information thus obtained, an index of each of these factors and a general home status profile can be determined.

Such environmental measures are sometimes criticized because they deal with things and factors in the environment and not with the effect of these things and factors upon the child. They record, for instance, how many books there are in the home and how much formal schooling the parents have had. They rarely take into account how much use the child makes of the books and what kind of conversations the parents have with their child. Not only are these criticisms important when high and low scores are interpreted in terms of favorableness-unfavorableness, but they also affect the possibility of valid comparison between two scores made on the same scale, unless that scale is very specifically named and it is understood just how narrow the variable is that has actually been measured.

For the teacher the measurement of the environment presents different problems than it does for the research worker. The teacher wants to know what there is in the home or neighborhood that can have an effective influence (good or bad) on the child, and what the effect actually is. The danger in his use

of existing rating scales is that he will infer certain influences which actually do not exist. If questionnaires on home conditions are used by the school, whether these call for ratings or for mere enumerations, they may well form the basis for a study and analysis of home influences. Their data should not, as they stand, form the conclusions upon which the teacher bases his guidance of the child. One of the most important reasons for the teacher's studying the child's home and community is so that he can help him to interact with those environmental factors which will be beneficial to him. Available scales and questionnaires may prove useful. Often, however, the school will have to construct a scale to suit its own community.

EQUATED SCORES—See SCORES, CONVERSION OF.

EQUATING GROUPS. Two or more groups are described as *equivalent* when they approach equality in one or more characteristics which may affect the operation of the experimental factor. *Equating* of groups in controlled experimentation is used to determine the net influence of an experimental factor. Equivalence of groups does not require that all the *subjects* participating in the experiment be equivalent, but it does mean that all the *groups* participating be equivalent. Groups may be equated in several ways. The most precise method is to pair individuals with respect to each of many relevant, measured traits. If individuals are so paired, the variability and the average scores of the groups will be identical. A modification of the ideal condition in the direction of feasibility is to pair individuals on the basis of a composite of the various traits. A more practical modification calls for the matching, not of individuals, but of groups on the basis of average score and variability

in each of several traits. The next procedure employs the matching of groups in average and variability with respect to the composite scores of several traits. A further move in the direction of practicability eliminates the consideration of the variability of the groups, retaining only equality in average score. Finally, the remaining trait might not even be measured but equated with respect to it left to chance alone. Where the number of subjects is large, and certain conditions are observed relative to random sampling (*q.v.*) procedure, chance is a highly exact basis for securing equivalent groups. Unfortunately, chance selection of whole classes, which is frequently the only practicable procedure, does not satisfy the conditions of random sampling and consequently may not provide truly equivalent groups. ERROR OF ESTIMATE—See PREDICTION OF SUCCESS.

ESCAPE TENDENCY. A behavior mechanism adopted by an individual to escape emotional conflict or other unpleasant realities. Thus, a child may blame a teacher and not his lack of study for his low marks; or the adolescent girl may escape from uninteresting reality by identifying herself with the heroine in a movie or novel. (See DAY DREAMING; MENTAL HYGIENE.) R.V.M.

ESSAY EXAMINATION. Essay examinations receive their name from the fact that they consist essentially of questions the answers to which are in the form of written expression by the pupils, or of topics or broad questions upon which the pupil writes essays or discussions. They are often termed *traditional* or *subjective* examinations in contrast with the so-called *new-type* or *objective* examinations.

The critics of the essay examination have centered their attack mainly upon its unre-

liability. Since about 1910, studies in many lands, covering a variety of subjects both on the high school and college levels, have shown wide disagreement among presumably equally competent teachers marking the same papers. Even more disturbing has been the discovery that the agreement is but little, if any, better between two series of marks assigned the same papers by the same teachers after an interval of time. A large part of the unreliability of the essay examination must be ascribed, therefore, to unreliability of *marking* or *grading* the examination. There is also evidence that the examination itself constitutes an undependable sampling of the student's knowledge. A study by Talbott and Ruch, for example, showed that the essay test called forth less than half the student's knowledge, as revealed by an objective test, and required twice as much time. Reliability coefficients obtained by correlating two different essay examinations, presumably covering the same material, have in general shown no closer agreement than those obtained from different markings of the same papers. The validity of the essay examination is reduced by the fact that so many extraneous factors enter into the writing and the grading of the answers. For example, a student's grade on a history paper is often influenced not only by his understanding of history but also by his ability to express himself in a manner that pleases the reader. The grade may be affected to no small degree by the unintentional comparison of each paper with the one previously read by the teacher; a mediocre paper may look good to a teacher who has just read an inferior answer, while it may be rated severely if it has been preceded by a superior paper.

Those who favor the essay examination have based their preference mainly upon its alleged superiority for measuring and for achieving certain important educational objectives. Unfortunately, little experimental evidence exists for determining just what are the unique functions measured by the essay examination. Logical considerations, however, suggest that the essay form of examination should be valid for such courses as English composition and journalism, and for certain aspects of other subjects, such as the student's ability to see relationships, to make evaluations and summaries, and to

apply his knowledge in an organized, effective manner to new situations. There is considerable statistical support for the conclusion that when students expect the tests to be wholly or partly of the essay type they are more likely to employ such desirable study procedures as making outlines and summaries and seeking to discover relationships and trends than they do when objective tests are used exclusively. This constitutes a strong argument against abandoning the essay examination altogether. There seems no escaping the fact that the nature of the examination influences the way students study as well as what they study.

Many of the objections raised to the use of essay questions are criticisms not so much of the essay question itself as a measuring instrument, as of the popular errors in the construction of the questions and in the scoring of the answers. The use of essay questions has much to commend it, provided the questions are constructed and rated wisely. Several suggestions for improving the construction and use of essay examinations deserve the teacher's attention. The use of the essay examination should be restricted to the measurement of those functions to which it appears best suited. Thus, the essay question is used more appropriately when it seeks to measure the student's ability to interpret and evaluate than when it elicits only the student's recall of specific factual material. Essay questions should be used in combination with objective questions to afford a more valid sampling of the student's ability. Optional questions should be eliminated since it is rarely possible to make all the questions on an examination of equal difficulty. The question should be worded so carefully that it indicates to the student the kind of answer that is expected of him. "Discuss the Monroe Doctrine" is a vague question, though it is of a type used widely. It is preferable to limit the student's answer, as in the question: "How have our changes in the interpretation of the Monroe Doctrine been related to changes in the foreign policy of the United States?" Keys of acceptable answers and definite instructions for marking the papers should be prepared before the teacher rates the answers; the keys may be modified after the teacher has applied them to a sampling of the answers. The

answers should be rated question by question rather than paper by paper so that the teacher reads all the answers to one question before proceeding to read all the answers to the next question. Any device for concealing the student's name until the answers have been read will eliminate another irrelevant consideration from influencing the ratings.

Such suggestions as those given above should improve the validity and reliability of the essay examination, but so far no way has been suggested for reducing the time required for the students to write the answers or for the teachers to evaluate them. In fact, the careful construction of essay questions and rating of answers will make even heavier demands on the teacher's time. (See EVALUATION; MEASUREMENT IN EDUCATION; AND OBJECTIVE TESTS AND EXAMINATIONS.)

ESSENTIALISTS, THE. Michael J. Demiashkevich (1891-1939), proposed the name *Essentialists* to designate adherents to educational theories that emphasize the transmission to each generation of the basic elements of human culture as the primary function of organized education. The significant contrast is with the adherents of the theories that emphasize education primarily as the promotion and direction of individual growth or development. Since the latter teachings are today represented chiefly by the so-called "Progressive" school of educational theory, the Essentialists have been regarded, not without reason, as critics and opponents of Progressivism.

Unlike the Progressives, the Essentialists have no large and influential organization to propagate their doctrines. In February, 1938, a very small group, numbering fewer than a score of persons, formed an "Essentialist Committee for the Advancement of American Education" under the leadership of Professor Demiashkevich and of F. Alden Shaw, headmaster of the Detroit Country Day School.

This Committee was organized at the time of the mid-winter educational meetings, which in that year were held at Atlantic City, and which, as usual, brought to the place of meeting thousands of educational workers from all parts of the country. It became noised about that this Essentialist group would, figuratively speaking, take up guns against the Progressives. This rumor had "news" value, and a statement regarding the Committee, together with some fragments from a set of theses that had been prepared for discussion but which had not been formally adopted or officially released, was sent out by reporters and received the attention of the press throughout the country. As a result the terms *Essentialists* and *Essentialism* became current, literally overnight, as the antitheses of *Progressives* and *Progressivism*.

Although the Essentialists are distinctly opposed to many of the tenets of the Progressives, they have had no disposition to deny that definite benefits have come to American education from certain theories and practices that the Progressives have supported and propagated. The differences between the two groups are primarily differences in emphasis. Through the long history of formal education, and formal education is almost as old as civilization itself, certain dualisms have developed and persisted, and educational theory for centuries has struggled to resolve them. These dualisms have been reflected in such paired opposites as interest *vs.* effort, freedom *vs.* discipline, individual desires *vs.* social demands. More recent discussions have added such paired opposites as immediate goals *vs.* remote goals, pupil-initiative *vs.* teacher-initiative, psychological organization *vs.* logical organization, activities *vs.* subject-matter.

In general, while both schools of theory recognize that each term of these pairs of apparent opposites represents a needed function of education, and while both schools attempt to find some integrating principle that will resolve the dualisms, the Progressives give the primary emphasis to the first of each pair of terms: interest, freedom, individual desires, immediate goals, pupil-initiative, psychological organization, activities; the Essentialists give the primary emphasis to the second term of each pair: effort, discipline, social demands, remote goals, teacher-initiative, logical organization, subject-matter.

From the point of view of the actual content and administration of the educational program, these differences in emphasis, which seem slight in theory, may lead to wide divergences in practice. Consistent Progressive practice, for example, frowns upon the assignments of learning tasks "imposed" by the teacher. All learning, it is held, should be at least motivated by the learner's recognition of its value; it would be even better if a demand for the learning came spontaneously from the learner's "felt need" for something to help him solve a problem or realize a purpose. The Essentialist would by no means object to learning that stems from such inherent motives and needs; he would not for this reason, however, assume that all learning activities must so originate; he would insist, indeed, that it is the primary duty of the teacher to see to it that the essentials are mastered by the learner systematically and sequentially, and that such systematic and sequential learning can be made by skillful teaching not only acceptable to the learner but often, and almost always in the end, interesting and inherently rewarding.

While at the present time the Progressive school of educational theory derives comfort and sustenance in large part from a single school of philosophy, Pragmatism, the Essentialists are drawn from many philosophical camps: Idealism, neo-Realism, Naturalism, Aristotelianism, and neo-Scholasticism. Such concepts as duty, system, order, thoroughness, and industry are emphasized by some Essentialists, who lean toward Idealism, neo-Scholasticism, or Aristotelianism, as partaking of the nature of absolutes, and by other Essentialists, who are neo-Realists, as ideals which race-experience has enthroned as standards of permanent human value. Progressivism follows Pragmatism in rejecting all absolutes and all assumptions of anything akin to permanent values.

It is highly probable that the controversy between the Essentialists and the Progressives, which flared out suddenly in February, 1938, is largely responsible for a greatly increased interest upon the part of educators in the philosophical systems that lie back of contemporary educational theories. The development of American education during the past generation has been powerfully influenced by the advances in what may be called the sci-

ence of education, especially through the rise and development of the measurement movement. It is significant that the advances in educational science, impressive though they are, have not as yet rendered any less important the activities of the educational theorist. It is indeed worthy of note that the towering figure in American education over a period of more than forty years has been John Dewey, who is not a scientist but a theorist—a philosopher. It should be remembered, too, that while Dewey's teachings are responsible for the latter-day teachings of the Progressives, he himself has indorsed, although not by mentioning names, some of the most cogent criticisms of Progressivism advanced by the Essentialists. ETHICS, PROFESSIONAL. In keeping with the widespread movement towards codes of ethics in the professions and many businesses during recent years, the National Education Association adopted a code of ethics in 1929 which was revised in 1941. The revised code follows:

PREAMBLE

Believing that true democracy can be achieved best by a process of free public education made available to all the children of all the people, that the teachers in the United States have a large and inescapable influence in fashioning the ideals of children and youth, and that such responsibility requires the services of men and women of high ideals, broad education, and profound human understanding, and in order that the aims of democratic education may be realized more fully, that the welfare of the teaching profession may be promoted, and that teachers may observe proper standards of conduct in their professional relations, the National Education Association of the United States proposes this code of ethics for its members.

The term "teacher" as used in this code shall include all persons directly engaged in educational work, whether in a teaching, administrative, or supervisory capacity.

ARTICLE I—RELATIONS TO PUPILS AND THE HOME

Section 1—It is the duty of the teacher to be just, courteous, and professional in all his relations with pupils. He should consider their individual differences, needs, the interests, aptitudes, and environments. He should not tutor pupils of his classes for pay, nor should he refer them to any member of his immediate family for tutoring.

Section 2—The professional relations of a teacher with his pupils demand the same scrupulous care that is required in the confidential relations of one teacher with another. A teacher, therefore, should not disclose any information obtained confidentially from his pupils.

Section 3—A teacher should seek to establish friendly and intelligent cooperation between home and school, ever keeping in mind the dignity of his profession and the welfare of the pupils. He should do or say nothing that would undermine the confidence and respect of his pupils for their parents. He should inform the pupils and parents regarding the importance, purposes, accomplishments, and needs of the school.

ARTICLE II—RELATIONS TO CIVIC AFFAIRS

Section 1—It is the obligation of every teacher to inculcate the principles of democracy. He should direct full and free discussion of appropriate controversial issues with the expectation that comparisons, contrasts, and interpretations will lead to an understanding, appreciation, acceptance, and practice of the principles of democracy. A teacher should not use his classroom privileges and prestige to promote partisan politics, sectarian religious views, or selfish propaganda of any kind.

Section 2—A teacher should recognize and perform all the duties of citizenship. He should subordinate his personal desires to the public good. He should be loyal to the school system, the state, and the nation, but he should recognize his right to give constructive criticisms.

Section 3—A teacher's life should show that education makes people better citizens and better neighbors. His conduct should not offend the accepted pattern of behavior of the community in which he serves.

ARTICLE III—RELATIONS TO THE PROFESSION

Section 1—Members of the teaching profession should dignify their calling on all occasions and should never minimize the importance of their services to society. On the other hand, they should not indulge in personal exploitation.

Section 2—A teacher should encourage the ablest individuals to enter the teaching profession and discourage from entering those who are using it merely as a stepping-stone to some other vocation.

Section 3—It is the duty of the teacher to maintain his efficiency by study, travel, and other means of keeping informed on trends in education and the social order.

Section 4—Every teacher should have membership in his local, state, and national professional organization, and should participate actively and

unselfishly in them. Professional growth and personality development are the natural product of such professional activity. Teachers should avoid the promotion of organization rivalry and divisive competition which weaken the cause of education.

Section 5—While not limiting their services by reason of small salary, teachers should insist upon a salary scale commensurate with the social demands laid upon them by society. They should not knowingly underbid a rival or agree to accept a salary lower than that provided by a recognized schedule. They should not apply for positions for the sole purpose of forcing an increase in salary in their present position; correspondingly, school officials should not refuse to give deserved salary increases to their employees until offers from other school officials have forced them to do so.

Section 6—A teacher should not apply for a specific position unless a vacancy exists. Unless the school system otherwise prescribe, he should file his application with the chief executive officers.

Section 7—Since qualifications should be the sole determining factor in appointment and promotion, the use of pressure on school officials to secure a position or to obtain other favors is unethical.

Section 8—Testimonials regarding teachers should be truthful and confidential, and should be maintained as confidential information by the school authorities receiving them.

Section 9—A contract, once signed, should be faithfully adhered to until it is dissolved by mutual consent. Ample notification should be given by school officials and teachers in case a change in position is to be made.

Section 10—Democratic procedures should be practiced by members of the teaching profession. Co-operation should be predicated upon the recognition of the worth and the dignity of individual personality. All teachers should observe the professional courtesy of transacting official business with the properly designated authority.

Section 11—School officials should encourage and nurture the professional growth of all teachers by promotion or by other appropriate methods of recognition. For school officials to fail to recommend a worthy teacher for a better position outside their school system because they do not desire to lose his services is unethical.

Section 12—A teacher should avoid unfavorable criticism of other teachers except that formally presented to a school official for the welfare of the school. It is unethical to fail to report to the duly constituted authority any matters which are detrimental to the welfare of the school.

Section 13—Except when called upon for counsel or other assistance, a teacher should not interfere between another teacher and a pupil in any matter.

Section 14—A teacher should not act as an agent, or accept a commission, royalty, or other reward for books or other school materials in the selection or purchase of which he can influence, or concerning which he can exercise the right of decision; nor should he accept a commission or other compensation for helping another teacher to secure a position.

ARTICLE IV—COMMISSION ON PROFESSIONAL ETHICS

There is hereby established a Commission on Professional Ethics operating under the Board of Directors of the National Education Association. This Commission shall consist of five members of the Association to be appointed by its president for terms of five years each, one term expiring on July first of each year.

In order that the Commission may begin functioning at once, it is recommended that the president for 1941-42 appoint five members who will draw for one-, two-, three-, four-, and five-year terms, respectively. Thereafter one member shall be appointed each year for a five-year period. The Commission will select its own chairman.

It shall be the duty of the Commission to study and to take appropriate action on cases of violation of this Code referred to it. The Commission also shall be responsible for publicizing the Code, promoting its use in institutions for the preparation of teachers, and recommending needed modifications.

If, when a case is reported, it is found to come from a state which has a code commission, such case shall immediately be referred to said state commission for investigation and action. In the case of a violation reported from a state which has neither a code nor a code commission, or where a state has a code but no code commission, the NEA Code Commission shall take such action as seems wise and reasonable and which will impress members with the importance of respect for proper professional conduct. Such action shall be reported to the chief school officers of the community and the state from which the violation is reported.

The Commission is further vested with authority to expel a member from the National Education Association for flagrant violation of this Code.

Almost two-thirds of the state teacher's associations had adopted codes before 1929. These codes of professional ethics serve as a guide to proper conduct among school administrators, teachers, and pupils in the daily relationship among older members. A code of ethics serves to bind the workers in a profession together and to give them a greater feeling of mutual confidence, esteem and respect. It demonstrates to the public the ideals of the profession. D.H.C. and A.R.A.

ETIQUETTE AS A SCHOOL SUBJECT. The teaching of the manners of the

day, the common matters of courtesy and etiquette, is a very old practice in schools. In the middle ages it was a matter of teaching the practices of chivalry. In the modern school it has received attention from a number of different angles. In the elementary school and to a certain extent in secondary schools, courtesy is taught through instruction and practice as a matter of good behavior, an expression of character. Such teaching stresses the fact that good manners should be only the surface expression of real character, that courtesy is born of thoughtfulness.

Another emphasis, given particular attention in secondary schools and colleges, is well expressed by a chapter titled, "Good Manners, a Vocational Asset," in a workbook on "personal analysis." This chapter impresses the student with the practical, selfish value of good manners, that to do the "right" thing pays dividends in vocational life. This emphasis has had considerable vogue and is strongly stressed in the "how-to-win-friends-and-influence-people" type of personality development fostered in many schools.

Clearly, the development of social polish, of courteous and mannerly behavior, and the mastery of the niceties of social living are no longer regarded as an aim only of the exclusive finishing school. The methods employed to teach good manners and etiquette are of various sorts. Etiquette is taught in some schools as a regular subject of instruction through the use of textbooks and all the other accoutrements of formal instruction. More commonly, however, good manners are taught as part of the work of less formal classes in guidance or through discussions in home rooms and elsewhere of the desirable qualities of personality. In elementary schools the give and take of classroom and school life offers numerous occasions for informal consideration of good manners. Considerable attention is given to etiquette in commercial courses, especially to the etiquette of business offices. In home economics courses attention is given to the etiquette of dining and social affairs.

That young people, especially in the high school and college, are concerned about etiquette is shown by studies of their interests and by the experience of teachers and guidance counselors. That their concern must find expression in experiences that will lead to

the development of those fundamental traits of character which will make good manners natural and easy is agreed to by educators.

G.E.H.

EURHYTHMICS, DALCROZE. This is a system of physical response to music in which the learner expresses through movement various musical rhythms and designs. It originated with Jaques-Dalcroze, eminent Swiss music educator (Vienna, 1865-). The program took form as Dalcroze experimented with methods for improving the rhythmic response of music students. He was seeking not only keen rhythmic perception but an improved sensitivity to musical components, such as dynamics, meters, phrases, melodic line, harmonic structure, tension, and relaxation. Students who pursue the course through several years apply the physical movement to refined instrumental technic and give special attention to the art of improvisation. The striking results of this work has spread to the musical capitals of the world through Dalcroze institutes. In America it has received its impetus by the work of Dalcroze's pupils at major universities and conservatories.

Purposes. Dalcroze has outlined the essential purposes of his system in the book, *Eurhythmics, Art and Education*, (A. S. Barnes and Company, New York, 1935). He states (page 3) that "[The object of] the rhythmic method of gymnastics... is to arouse and develop, by repeated exercises, the natural rhythms of the body." He maintains (page 106) that "nine out of ten children take up the study of a musical instrument without having music within themselves. Hence, the teacher has a dual task... to initiate into the mechanism of the instrument a muscular apparatus ignorant of its own mechanism, and also to bring his pupils into a condition to express, on an alien body, feelings which their own body has never experienced."

In addition to these purposes, Dalcroze claims other values for his system. He maintains that it strengthens the will, improves the memory, develops character, and "enriches the brain." Those who question the validity of faculty psychology attach little significance to these generalizations.

Use in public education. Teachers

generally accept the basic thesis that children need to feel music physically before they can express it. Adaptations of the Dalcroze method appear to rest on these assumptions: (1) The physical co-ordination of musculatures may be expected to transfer to related activities. (2) Large muscular movement is more vivid and meaningful as an embodiment of specific musical designs than are narrow musculatures or mere intellectual concepts. (3) Body rhythmic help release certain emotional tensions and consequently promote integration of personality. (4) Rhythmic movement of the body in company with other people tends to promote sociability. (5) Eurhythmics can be an enjoyable experience which may arouse a desire for other musical activities.

The Dalcroze method usually appears in public schools only in some form of adaptation because of limitations of teacher training, plant facilities, and purposes of the school. Instructors of music usually attempt to transfer from the physical movement to actual musical performance as soon as practicable. Physical education teachers generally carry the program toward a culmination in the dance. Some common uses of eurhythmics at different levels are given below.

In primary grades, children experience beats through walking, clapping, hopping, galloping, and swinging their arms to music. They walk the rhythm of songs to identify note values. At first, such terms as "walking notes," "running notes," and "standing notes" are used. From this terminology they progress to the traditional names and the staff notation. Children sense the form of compositions by discovering the number and similarity of phrases. While singing or hearing a song they move their arms or walk in a continuous line until a "resting place" occurs in the music; then they change the direction of movement until another phrase begins.

In the higher grades, children adapt some of the arm movements to the beating of time. In more advanced groups they may walk with an accent recurring in one meter and move their arms with an accent in another meter.

At the high-school level Dalcroze principles are used for the creation of dances. For example, a class may form two groups,

one becoming an outer circle, the other an inner circle. The students in the outer circle might move in one direction, walking, leaping, and swinging arms according to the melody of a piano composition. The students in the inner circle might move in the opposite direction performing similar movements to a counter melody of the same composition. The Bach *Two-Part Inventions* are sometimes interpreted in this manner.

Where adequate pianists are not available, schools have used phonograph recordings. However, the inflexibility of recordings limit their usefulness, especially when a creative response is desired. Sometimes a drum and vocalization of rhythm are used for accompaniment. Teachers seeking to develop skill in Dalcroze methods generally find it expedient to enroll in eurhythmic classes. Through their personal experience they sense more fully the purposes and technic of instruction. (See MUSIC APPRECIATION; MUSIC EDUCATION.)

EUTHENICS. Euthenics is a term used to describe all systematic efforts to improve humanity through changes in controllable environment; for example, improved health through balanced and regular diet, better sanitation and housing conditions, and adequate medical care are classed as euthenic measures.

R.V.M.

EVALUATION. The term *evaluation* frequently is used to refer to a great many informal situations in which one or more persons consider what value has followed from some particular experience. For instance, a class of children with their teacher may look back over the unit of work they are completing and consider what value the activities of the unit have had for them as a class and as individuals. Similarly, a

group of adults who have met together as a workshop group, or as a conference or convention assembly, may evaluate their experience together. They may consider informally in what ways their meetings have been worthwhile and in what ways future meetings may be of even more value to the group and its members. A student preparing to become a teacher may confer with his adviser about the contribution his past experiences have made to his professional growth, and about the potential contribution other experiences might have made. Such evaluations may be made quite subjectively through discussion, or they may be made somewhat more objectively by administering appropriate tests or by having questionnaires answered by the people concerned.

Evaluation may be thought of as a process in which four main questions are considered: (1) What are we trying to do? (2) What are we actually doing? (3) How does what we are doing compare with what we are trying to do? (4) How can we make what we are doing more nearly like that which we would like to do? Stating these phases of evaluation more technically we have: (1) defining the objectives, (2) using evaluative instruments and techniques in determining status and changes in status, (3) using appropriate statistical techniques in interpreting findings, and (4) setting up procedures by which improvements may be put into practice. These four steps constitute a cycle which will be repeated as the continuous process of evaluation goes on. The writings of Ralph W. Tyler⁵ describe, and his evaluative studies³ exemplify evaluation in a complete sense of the word.

If a person, a class, or a curricular program is to be appraised, the objectives must first be made explicit. What is being attempted? The answer to this question will result in a series of statements of objectives, each statement describing a kind of behavior expected of each student in specific situations. (See OPERATIONAL DEFINITIONS.) Such objectives will include some easily measurable forms of student behavior, but the list of objectives will probably include some that are not measured readily. The recall of specific facts and the performance of definite skills, like that of typewriting, will be appraised; but less tangible objectives,

which are of even more importance in living, will also be studied. Evidence should be obtained about other phases of student behavior: attitudes, interests, appreciations, health and other habits, critical thinking (including the ability to apply principles, to interpret data, and to present logical proof), personal-social relations, reading and other skills, philosophy of life, and the ability to interrelate these various aspects of behavior.

The method of evaluation is dependent on the objective to be appraised. Where appropriate standardized tests are available, they are used by evaluators, but the techniques for evaluating what is being done need not be limited to pencil-and-paper tests. For example, no pencil-and-paper test has yet been constructed by means of which the work habits of a student can be appraised adequately. If the work habits of a certain student are to be studied, his methods of working can be observed at regular intervals, and a notation made about them at each observation. These notations over a period of time constitute a record which shows the extent to which the student's work habits have changed during the time he was under observation. Similarly, anecdotal records, (*q.v.*) the recordings of overt behavior in picture or in sound, and student diaries may be utilized in appraising student behavior in process. To evaluate student attainment, one can examine critically such final products as paintings, musical compositions, dramatic performances, as well as oral and written reports. Evaluative reports are characterized by many faceted descriptions. A single instrument or technique of appraisal will yield a series of scores for each student. These multiple scores give a profile picture of the student and make it possible to diagnose difficulties he may be having and to work with him to further his maximum development. According to Troyer⁴, the interpretation of that profile picture is one of several phases of the appraisal process which should be a cooperative enterprise for student and teacher. Responsibility for interpreting and explaining what test scores mean, and for planning further activities in the light of these interpretations, should rest on the student as well as his teacher.

Evaluation is used significantly in curriculum improvement. To have an evaluative

study contribute maximally to the development of a curricular program, teachers, pupils, parents, and all others concerned with the program to be evaluated should participate in the study. An evaluative study should be an integral part of the educative process, continuing as the program continues. Evaluation results will suggest improvements to be made in the program and its objectives. At the same time, the evaluation process itself will contribute to the in-service development of teachers, and to the increased educational understanding of parents and patrons.

When worked out appropriately, an evaluation program will serve many purposes. It will provide a basis for grading, grouping, and promoting students; for reporting to parents; and for advising expenditures of school funds. But it will go beyond that by providing a means for guiding each student wisely; for working cooperatively with parents in promoting educational activities within the community; and for analyzing and improving the basic philosophy on which the school is functioning. EXCEPTIONAL CHILD. Educationally, the exceptional or atypical child is one who deviates mentally, physically, or emotionally from the average to such an extent that he requires special school provisions. These children are usually classified as: (1) the gifted, (2) the mentally defective, (3) the physically handicapped, and (4) children with behavior and personality problems.

There is an absence of definite standards of superiority, and children have been called *gifted* whose I. Q.'s varied anywhere from 140 and above to as low as 110 (provided the latter had good work habits). Thus, children from the upper one to ten per cent of any age group are included. A number of traits characteristic of gifted children have been listed, but these are not possessed invariably by all of them. Generally, however, the gifted child is superior mentally, physically, socially, morally, and educationally. The following types of educational provisions for gifted children have been tried, but their relative effectiveness has not been adequately determined: (1) acceleration, (2) enrichment, and (3) special classes. Acceleration includes extra promotions for individuals, rapid advancement by groups, and sectioning. The major criticism of this method is that it advances children educationally too far beyond their physical and social development. The 1930 White House Conference (g.v.) endorses enrichment which includes more challenging types of experiences, supplementary reading, and creative work. The special classes provide enrichment, acceleration, or a combination of the two. These classes have been objected to on the ground that they are undemocratic and make the child snobbish. If each individual is to have educational opportunities commensurate with his abilities, this procedure is not undemocratic and, furthermore, competition with his equals stimulates the gifted child. (See ENRICHED CURRICULUM; GIFTED CHILD, EDUCATION OF; and SPECIAL CLASSES.)

Experts differ in their concepts of *mental deficiency* (g.v.). However, one authority estimates that from 4 to 5 per cent of children in an average elementary school need special attention because of mental subnormality. From the standpoint of the public school a distinction must be made between those who are educable and those who are merely train-

able; an I.Q. of 50 is generally used as the lower limit for admission to school. The vast majority of subnormal children are enrolled in the regular grades, where they are promoted by age rather than by achievement, thereby avoiding the effects of failure and discouragement. This practice is unsatisfactory, however, since the average curriculum is not adapted to the needs of the slow child. In some cities special classes are formed for these children, in which methods and materials are adjusted to the child's intellectual level and where the child is trained in habits of effective citizenship. Selection of children for such classes should be done by experts, and an inoffensive term should be used to describe them. Where special centers are organized, transportation must be provided, but special centers have the advantage of more efficient grading and equipment. The principal objection to special classes or centers is that subnormal children are often isolated and stigmatized. To avoid this, the present trend is to allow such children to participate with normal children in as many ways as possible.

Physically handicapped children are usually defined as those who, because of some physical defect, congenital or acquired, are unable to progress normally in the ordinary school. These include three groups: (1) the blind and partially seeing, (2) the deaf and hard-of-hearing, and (3) the crippled, cardiac, anemic, tuberculous, and malnourished. There may also be combinations of any of these groups. (See HANDICAPPED CHILDREN.)

A child is considered *blind* whose vision is so defective that tactual methods, such as the Braille system must be used in his education. (See TOUCH READING.) These children usually are educated either in state residential institutions or in special classes which are a part of the public school system. Advantages claimed for the latter plan are that blind children are not isolated socially, and do not become estranged from their homes. Institutions, however, may have more elaborate equipment and may be better for children from poor homes.

A *partially-seeing child* is one who can be educated by visual methods, but whose sight is so impaired as to necessitate some adaptation of conditions and materials, e. g., special lighting, books in large type, etc. These

children are usually placed in special sight saving classes where, in addition to the customary instruction, the development of habits of sight conservation is emphasized.

The *deaf child* is one whose hearing is so defective that it is impossible for him to receive instruction by auditory methods; he must learn to understand language visually through speech reading (oral method). Such children usually are educated in state residential institutions or in special public school classes, and the relative advantages and disadvantages of these two plans are approximately the same for deaf as for blind children.

The *hard-of-hearing* child may suffer from serious hearing loss, but can still be educated by auditory methods, with the help of amplifying devices (hearing aids), supplemented with speech reading. These children often are found in residential schools for the deaf, but the modern trend is to educate them in special public school classes where they can associate with normal children. (See DEAF, EDUCATION OF THE; SPEECH READING.)

The education of *crippled, cardiac, anemic, tuberculous, and malnourished children* is concerned more with the treatment of their physical condition than with academic problems. They are usually cared for in orthopedic schools or hospitals, convalescent homes or sanatoria wherein environmental conditions and class work are adjusted to their handicaps.

"*Problem children*" are those who have behavior or personality difficulties which lead to problems for themselves or for others, or, sometimes, for both themselves and for others. In some instances, the child's emotional difficulties find expression in a manner that creates no overt problem to concern others. Such a youngster, for example, may be fearful or unhappy and yet behave well enough in school to make an apparently good adjustment to the school situation. With other children, however, the youngster's emotional difficulties may lead to the kind of conduct that is in conflict with the social standards of the home, the school, and the community. Children's maladjustments may be caused by such personal inadequacies as mental retardation, physical handicaps or illness, warped personalities, or by frustrat-

ing environmental influences, such as homes of poverty and vice. In progressive cities these children are referred to Child Guidance Clinics where the child's personal history is studied and recommendations are made for his future development. These may include more adequate school placement; special methods, or more effective teaching procedures; change of teacher; re-educating members of the family; or removal from the home or community to a foster home or correctional institution. (See articles on such topics as: SPECIAL ABILITIES; GIFTED CHILD, EDUCATION OF; HANDICAPPED CHILDREN; etc.) F.K.M. and R.V.M.

EXCURSION—See TRIP, SCHOOL.

EXHIBITIONISM. This term originated in psychoanalytic psychology, and in one sense is associated with the exhibition of certain parts of the body, especially the genitals. In its wider and more modern usage, however, it is employed to describe any attempt made by an individual to become the center of attention.

Instances of sexual exhibitionism may be found in the school room, on the school grounds, or in the toilets. It may include either exposure of the body or the drawing of obscene pictures. Strict but unobtrusive vigilance should be exercised to combat this situation. Such behavior is often symptomatic of ignorance, maladjustment associated with sex, or it may result from an attempt to over-compensate for feelings of inferiority—real or imagined. In such cases the motives must be determined before the problem can be solved, and the services of a clinician should be enlisted.

Adolescents are particularly prone to the latter, more general type of exhibitionism as evidenced by their desire to make an impression by wearing flashy clothes, talking loudly, telling questionable stories to shock others, bragging, etc. Although these tendencies are annoying to adults, they are, for the most part, evidences of immature but normal attempts to get social prestige, or serve as defense mechanisms to compensate for inferiority. Participation in dramatics or athletics has been suggested for those adolescents or adults who show this behavior to an excessive degree. On the other hand mere participation in dramatics or athletics may be ineffective if the exhibitionism is a symptom of more serious emotional maladjustment. (See DEFENSE MECHANISM; MENTAL HYGIENE.)

EXHIBITS, EDUCATIONAL. The educational exhibit offers the opportunity to bring a "slice of life" into the classroom. Many ready-made exhibits are available to schools willing to pay the cost of transportation. The exhibits which are available from museums, government organizations, commercial and semi-educational agencies are constructed with a view toward telling a story in a strikingly graphic manner. They usually consist of posters, charts, maps, specimens, models, pamphlets; and sometimes have accompanying slides, filmstrips, and motion pictures. They are loaned to the schools for limited periods of time. Most science supply houses sell exhibits of natural science materials and many schools utilize this material in building up school museums. A great deal of exhibit material may also be obtained from industrial concerns which give the material away or sell it at a small cost. Such so-called free material should be examined carefully for school use, for, although much of it is extremely valuable, the schools run the risk of using the classroom as a disseminator of advertising propaganda. Still another source of exhibits is the school environment. Specimens of leaves, stones, insects, and historical

remains may often be found easily. Another valuable source of material lies in the homes of students. This is especially true of articles used as exhibits in the social studies such as costumes, household articles, old newspapers and theater programs, and other articles reflecting ways of life in other times or in other parts of the world.

The school exhibit can be utilized as a form of concrete experience with the environment. Properly arranged exhibits offer opportunity to see, handle, smell, and hear. The student may even put a process into actual operation by the use of mechanical models. Student cooperation in properly organizing, labeling, constructing and displaying exhibits should be encouraged. Care must be taken to avoid the tendency to allow exhibits to become an end in themselves in which the students use an undue amount of time in construction, collection, and arrangement, perhaps losing sight of the educational ends which the exhibit is meant to serve.

EXISTENTIAL PSYCHOLOGY — See PSYCHOLOGY, SCHOOLS OF.

EXPERIENCE CURRICULUM. An *experience curriculum* is composed of a series of purposeful experiences growing out of pupil needs and moving through a democratic process of exploration, critical inquiry, deliberative action toward an ever more adequate understanding of and participation in the surrounding culture and group life. The basic experiences for study develop from pupil needs which arise out of their interaction with their environment. The process is deliberative, cooperative, social. The present is the time center in the study of the need. The past and the future are examined and weighed in so far as they are data upon

which to make a more thoughtful present course of action. The controlling outlook is always in terms of consequences of present action upon ability to reach more reasonable judgments tomorrow. The continuity in a series of experiences lies in the quality of the learnings which are picked up from one to carry on to another. This quality is contingent upon the process of selection and study of the need together with the logic of organization of the learnings, both of which are tested in the developing experience. The study of each need culminates in a satisfactory feeling tone for each person actively participating.

Since a difference between a subject curriculum or any one of its many variations and the experience curriculum lies in the quality of the experience, the learning of the most traditional subject matter is an experience for those pupils who pass or fail. Advocates of the experience curriculum hold that there is little necessity for the school to promote a low quality of experience of the subject type since more meaningful experiences with subject matter can be found in many other life associations. The school must help the pupil improve his relationships with his environment by rising above the common level of learning and action. Thus the experience curriculum implies a clean break with all forms of existing variations of the subject curriculum together with the basic ideas of human relationship, control, learning upon which they are founded. This, of course, does not mean a break with the culture, as it is impossible for anyone to be born or to live without a culture. The break is only with the current selection and organization of those parts of the culture which are the essentials for teaching in the schools.

An important consideration in the experience curriculum is the *total growth* of all learners rather than some selected aspect of total growth such as the development of abstract reasoning for one group of learners, which is found in subject curriculums. Furthermore, the relative values of the many interrelated aspects of total growth are re-examined. Emphasis is given to those which are near the center of behavior and become a part of the self, such as feelings and attitudes, beliefs and values, emotional stability, personal integration. Objective knowledge

and refined skills must operate through these more human and personal controls which have a lasting effect upon behavior. And the advocates of the experience curriculum want to recognize the *total life* of the school which includes the living of children, teachers, parents and others who affect in any way the quality of child development. Since the total living educates the total child, the school must help each child learn how to manage his living in order to keep it on as high a plane as possible. Thus the experience curriculum becomes synonymous with improved living although it is frequently confused with other types which attempt a more limited reorganization in *some one aspect* of total growth. All individuals, young and old, really learn what they live, and live what they learn. (See ACTIVITY PROGRAM; CURRICULUM; PROGRESSIVE EDUCATION.) L.T.H.

EXPERIENCE METHOD IN READING—See READING, METHODS OF TEACHING.

EXPERIMENTAL EDUCATION. Experimental education as here discussed means the kind of education carried on in an experimental or laboratory school. Such a school is experimental, first, in that the school program is, by the way it is built, in continual process of experimental determination and, second, in that the program so built is itself an experiment in building the kind of mind and character needed for continual growth in and toward the life counted good.

To illustrate in current terms, suppose those running such a school conceive education as the conscious effort to assist and guide the young in growing up effectively into social life—to live well in it, to help carry it on, and to improve it. Suppose, further, that they accept democracy as the desirable way of life and, still further, believe that anyone—child or adult—will learn anything for living purposes only as he lives that thing in its life-setting, both in his heart and in his consistent outward conduct. As the teach-

ers in such a school seek to provide suitable living conditions and beyond that try to stimulate, elicit, and guide the pupil-living so that it will result in the kind of mind and character needed for continual growth in dynamic democratic living—as the teachers do so try, and in the degree they try, their effort will be characterized by continual experimentation. The educative results, socially considered, must be under continual criticism as to the degree in which they confirm the things experimentally done and the principles on which they were experimentally based. It is in these respects that such education is called experimental.

Experimental education of this kind, as history shows, has usually sprung from an interest in reform, typically social reform, though the concern may be more specifically for improving education itself viewed simply as a needed life process.

This is of course not the only type of experimentation to be found in educational work. Another fairly common type is quite similar to the experiments usual in psychological laboratories. In this type any detail of schoolwork may be studied with reference to the comparative merits of different ways of conducting it. Actual instances have been the effort to determine the effect of class size on learning results, to compare the respective merits of two methods of teaching reading, spelling, and subtraction, and even to determine the comparative effects on examination results of the presence or absence of arm rests on the seats used. In such experimentation the ordinary scientific precautions will properly be stressed: only one significant variable must be involved; a control group is necessary, etc. This type of experimentation is "scientific" in a sense not seemingly true of the other.

As we contrast these two types of experimental education other significances appear. For one thing, the scientific experimentation is, at least for thought and often in fact, quite separable from the essential school program. As regards immediate aim in view, the two—experiment and school program—need have little or nothing in common. The exact opposite of such a separability holds of the experimental education of this article; in it both the immediate aim and the content of the experiment are part of the essential content and aim of the schoolwork. As we

think further about the matter and note that the aim here is in each case to make life better and that the content is in each case the best living we can manage—as we note this constant emphasis on the quality of living, we see that philosophic questions enter naturally and even necessarily. It then becomes easy to say that as the one type of experimentation is “scientific,” the other is by contrast “philosophic.” The latter must consciously consider what makes life good and how the various constituent factors of the good life interact to effect that end.

If we think historically of an experimental school movement, Pestalozzi, the Swiss (1746-1827) (*q.v.*), should probably be named as its most prominent initiator. He was moved strongly by the humanitarian and democratic tendencies of his day and sought a type of school to foster these desired reforms in society. It seems also true that a profound love of children was a significant factor in his work. Herbart (*q.v.*) hardly belongs as a personal exponent of this particular movement, though various “Herbartians” who maintained experimental schools do. Froebel (*q.v.*), with Pestalozzi, definitely belongs in the movement. How these men have changed modern education and how their actual schools were powerful aids therefore are matters of history.

In America the training school at Oswego, New York (whence the “Oswego movement” of the 1860’s), the Quincy (Massachusetts) schools (1875 ff.) under Francis W. Parker, the John Dewey “Laboratory School of the University of Chicago” (1895-1903), Miss Patty S. Hill’s Kindergarten (1907 ff.), and the Lincoln School of Teachers College (1917 ff.) are outstanding instances of experimental schools that have significantly affected American educational practice.

Is there a continuing future probable for experimental education as here presented? The answer seems certainly yes. As long as civilization develops new problems and psychology new and more adequate insights, so long must education develop new insights both as to goals and as to procedures. Continued experimentation will remain a continuing need.

W.H.K.

EXPERIMENTATION IN EDUCATION—See EXPERIMENTAL EDUCATION; RESEARCH, EXPERIMENTAL.

EXPLORATORY STUDY. As applied to study, *exploratory* implies a general search or view of a topic or problem. This kind of study brings out the scope and boundary of an area of learning; it provides a rough idea of its implications; and it aims at awakening and discovering student interests and special inclinations. A class in civics, for example, may be approaching a new phase of its work—conservation. Instead of assigning a part, such as the conservation of forests, the instructor opens the whole problem from all angles. This exploratory work will get pupils to read, to observe, and to investigate; it will reveal that class members may discover such ramifications of the problem as the conservation of birds, flowers, and natural and human resources. At this point, conservation can be delimited to those aspects to be studied by the teacher and the class. Exploratory study enables the pupils to view the whole area of learning before going into details; it encourages a certain approach to problem-solving; and it fosters evaluation of the importance and weight of phases of study. It is, of course, more time consuming than the kind of teaching in which topical assignments are made and textbook study begins immediately.

In addition to the use of exploratory study within a single subject, there has been a trend toward the organization of entire courses that are exploratory in nature, so that the student has the opportunity of surveying a general field to find his interests and the teacher can discover aptitudes and exercise guidance. This exploratory function, among others, can be given to such courses as general science (See SCIENCE, TEACHING OF.) and general language (*q.v.*) in the junior and senior high schools, and to science survey and contemporary civilization courses at the college level.

EXTENSION EDUCATION—See UNIVERSITY EXTENSION.

EXTENSIVE READING—See READING, EXTENSIVE.

EXTRACURRICULAR ACTIVITIES. The term extracurricular activities is a loose designation for those school activities outside the traditional school curriculum. The line between curricular and extracurricular activities has always been vague and many for-

EXTRACURRICULAR ACTIVITIES

mer extracurricular activities are now part of the regular program. The growing recognition of extracurricular activities is indicated by the fact that this field, neglected prior to 1920, now has more than sixty books as well as one specialized journal (*School Activities*, 1515 Lane Street, Topeka, Kansas).

A major object in furthering extracurricular activities is to stimulate and develop the habit of engaging in worthwhile, personality-building, leisure-time activities.

Extracurricular activities contribute much to the school program. They make use of the student's innate drives and urges by directing his free activities along channels that are educationally worthwhile. They help unify the school and foster the development of school spirit.

Basic Principles. (1) The student is a school citizen. Extracurricular activities should provide a setting in which he sees his duties as well as his privileges. (See CITIZENSHIP, EDUCATION FOR.)

(2) These activities should be included in the regular school schedule and the sponsor's efforts should be recognized as part of his program. This not only makes for good student and teacher attitude and gives added importance to the program but also helps assure a correlative demand that the time and effort be well spent.

(3) Activities should be correlated closely with the curricular work. Thus athletics may tie in with health education, and publications, with English. (See ATHLETICS and PUBLICATIONS, SCHOOL.)

(4) Wise participation should be encouraged. All students should be encouraged to participate but no student allowed to monopolize the responsible positions.

The most common means of limiting participation are: (a) simple limitation, with no student permitted to engage in more than a given number of activities; (b) a point system, where activities are evaluated according to the amount of time required and no student may carry more than a certain number of points; (c) major and minor activities, with the student limited to a certain number of majors and minors; and (d) a group system, where all activities are classified into such groups as sports, academic, service, etc., and the student is limited to one activity in each group.

Student participation is encouraged by (a) granting awards, as letters and pins; (b) allowing credit toward graduation; (c) appointing to a position of honor, as marshal; and (d) conducting social functions such as trips. Although there are some arguments in favor of compulsory participation, this method is not popular. The only valid requirement for participation should be a vital interest in the activity. Even the minimum ability requirement usually set by such organizations as dramatic and athletic groups may be questioned, since one of the primary aims of these organizations is the discovery and development of these abilities.

(5) Extracurricular programs should be developed gradually and should meet the school's special needs. Though any school may gain much by examining the program followed by another school, little can be said for the unimaginative adoption of an entire program that may not fit the local needs. Further, no good program is permanent; it must be adjusted constantly to meet changing conditions.

(6) Competent administration and supervision are essential. In the smaller schools, the principal is normally the person who supervises these activities, but in medium or larger sized schools there is usually an assistant principal, a dean of students, or a director of activities. A faculty committee often works with such an administrator or takes the place of the special officer.

Developing and maintaining the faculty cooperation necessary for a well-organized program are major problems. Almost every school has some teachers who have developed their activities to a high degree of success while others believe these activities to be a waste of time; some teachers are willing but untrained and incompetent, others are trained and competent but unwilling.

The individual faculty sponsor carries a major responsibility. The students of one high school described the "ideal sponsor" as having the habit of allowing the students to assume most of the responsibility, tact in directing the choice of programs without letting the students feel he is interfering, the ability to make friends with students on an informal basis outside of class, a sympathetic understanding, a knowledge of the subject on which his activity is based, a strong

and pleasing personality, and a sense of humor.

(7) The financial organization is often inefficient, possibly as a result of the marginal position that these activities have formerly held. In the decentralized form of financial organization each activity raises and disburses its own funds. This procedure is inferior to the centralized organization where all funds are collected and disbursed by a central office, which assures adequate financial support for all worthy activities regardless of their income and encourages the employment of auditing, bonding, and other businesslike procedures.

The most logical source of income for extracurricular activities is the grant from the board of education. School boards have generally provided indirect support by purchasing equipment and supplies, paying for the teacher's time, etc., and they are providing increasing support not only to assure equitable financing of all activities, but also to make certain that the stress is placed on educating the participants and not on collecting large gate receipts. Where such support is unavailable, activity tickets are often sold, sometimes on a partial payment plan. The student pays a fixed sum which admits him to all events, entitles him to the newspaper, etc. This procedure assures fairly accurate budgeting and renders unnecessary the various slipshod money raising schemes so often employed, with attendant uncertain financial return and dubious educational implications.

(8) Extracurricular activities should be evaluated continuously for their immediate and ultimate effect, employing the interested efforts of all who are engaged in these activities, and using all available valid techniques. The immediate effects of participation are important, but not nearly so important as the ultimate effects. Evaluating the ultimate effects is admittedly difficult, but it must be emphasized. The evaluation may be based on the extent of participation and the nature or quality of participation. One can assume that the greater the extent of volunteer participation, the more attractive and successful is the program. Yet a student may participate to so small an extent that he may be little better off than if he had not participated at all.

Evaluations of quality are difficult, but judgments of apparent interest, industry, and

achievement give some indication of the quality of participation. Most of the evaluation of extracurricular activities will be necessarily subjective, taking the form of expression of likes and dislikes, rating cards, etc. These judgments may be obtained from participants, former participants, and other competent critics.

Controlled experimentation is rarely found in extracurricular affairs. Experimentation in this field usually represents a change from previously used materials and techniques. Rare is the serious attempt to discover the reasons for the previous failure and even rarer is the published account of the failure, even though the analysis of failure may be valuable to those working in the field.

EXTRAMURAL COURSES. Courses given off the campus. They may be offered either by correspondence or by classes at the places of instruction. They are also called extension courses. In 1891 there was organized in Chicago a society for the extension of university teaching, to be directed by public library agencies. Today most of these courses are directed by the individual colleges. Massachusetts, with a separate organization, is an exception.

The major advantage of extramural courses is that they enable the sponsor institution to extend its influence and facilities to accommodate students who cannot attend courses conducted on the campus. A state university, for example, may conduct courses at centers located in various parts of the state and thus enable teachers to continue their own studies

even though the lack of time and the pressure of the other duties do not allow the teachers to travel to the university campus during the school year. Extramural courses also make it possible for an institution to take advantage of the wealth of resources in the community. A course in art appreciation, for example, may be conducted more effectively at a museum than at the college, and the course in astronomy may be more meaningful if it is given at a planetarium. Those who tend to belittle the value of extramural courses refer to the temptation to lower the standards when the work is done at centers far removed in space, and possibly in atmosphere, from the sponsor institution. Criticism has been leveled, too, at the inadequate library and laboratory facilities usually available for students of extramural courses and point to such inadequacy as both a symptom and a cause of lowered standards.

Most institutions count some extra-mural work (limited in amount) toward the degrees. Correspondence work is usually accepted in less proportion than other types.

FAMILY LIFE, EDUCATION FOR.
In the broad sense *education for family life* includes any instruction or guidance which is designed to help members of families participate happily and usefully in family life. Education directed specifically to parents as parents, or to young people in their capacity as future parents, is, however, to some extent distinguishable from the more general "education for family life," which deals with all relationships within the family, and with the functions and goals of the family as a whole. (See PARENTAL EDUCATION and PRE-PARENTAL EDUCATION.)

The recognition that family life is a subject in which education can profitably be undertaken has been brought about by several factors: (1) the impact of socio-economic changes upon the family as an institution which have created a need on the part of family members for guidance in adjusting to these changes, and for help in strengthening those important functions of the family which remain unchanged; (2) the attention focused on family relationships and adjustments by the rising interest in mental hygiene on the part of both laymen and specialists; (3) the increasing desire on the part of educators to

physical needs of their students. Such crises meet the social as well as the intellectual and as economic depression and war have also concentrated attention on the status of the family.

Courses on family life in colleges and high schools have multiplied rapidly since 1920, though they are not yet offered by all institutions. College courses taught by one specialist or a group of specialists now usually include sociological material on the family and marriage as institutions and on the relationships between the family and the community; psychological material on personality development, age and sex differences, family relationships, and family goals; and some information on techniques of home management, which may be demonstrated in actual homes set up for teaching purposes. An attempt is being made in some colleges to meet the needs of men as well as women, mixed groups being admitted to the courses in several institutions. Individual counselling by psychiatrists or deans often supplements formal instruction and informal discussion groups.

Where special high school courses on family life exist, they tend to resemble those in the colleges, except that the material is simpler and more concrete, and the emphasis less on preparation for future family life than on the adjustment, often difficult during adolescence, to present family situations. Some high schools which do not offer special courses attempt to treat problems of family life in courses in home economics, biology, or psychology. Education for family life is also offered to young people of school and college age by various non-academic organizations, such as the 4-H clubs, and the YMCA and YWCA. Below the junior high-school level, education for family life is necessarily more informal and indirect; it has not played a large part in elementary education generally, although its possibilities are being

realized increasingly in the primary grades through activity programs and dramatic play.

For adults who have established families of their own, education for family life centers largely about parental education. Instruction dealing with other aspects of family life is offered, however, in some university graduate and extension courses, by adult education programs serving rural communities, by social case workers of private and public welfare agencies dealing chiefly with underprivileged groups, and by a wide variety of books and periodical articles of all levels of difficulty. Of increasing importance, also, is the work of special services like the Family Guidance and Consultation Service of the Child Study Association in New York City, or the Institute of Family Relations in Los Angeles, which provide consultation on marriage and family problems for persons of all ages. (See also PRE-PARENTAL EDUCATION, PARENTAL EDUCATION.) B.B.L.

FASCIST EDUCATION — See ITALY, EDUCATION IN.

FATIGUE. While *fatigue* may be defined as decreased ability in performance resulting from prolonged work, certain factors in the situation may cause fatigue to set in relatively early. The "feeling of fatigue" experienced by a person is not directly proportional to the amount of work he has done. Neither is the decrease in performance directly proportional to the length of time that has been devoted to work. Physiological studies of muscular fatigue indicate that the consumption of

energy-producing compounds and the accumulation of waste products are relieved by periods of rest and sleep. Factory studies have shown that increased output can be brought about not only by shortening the work day and interspersing rest-periods, but also by changing the attitude towards the job and the relation of workers to each other and to the management. Furthermore, laboratory experiments have shown that when the subject refuses to go on with a task because of what he describes as "such fatigue that it is impossible to continue," a very slight variation of the task, with the same muscles involved, (such as the writing of dots in pairs rather than singly) will cause the subject to resume the work and continue for some time with no more rest than the time taken for the momentary refusal.

The work situation in school and elsewhere may be complicated by emotional tension caused by such a requirement as sitting still or by anxiety about success. The school pupil is affected adversely also by monotony and boredom, which are difficult for him and his teacher to distinguish from fatigue. On the other hand, under the stimulus of vivid interests, children and older persons may continue working effectively for relatively long periods on one project, or on a series of varied activities.

Fatigue appears to be relative to the whole learning situation involving many factors and to be so related to personal attitudes and interests that school practice must be established as far as possible on the basis of the total development of each individual. To say that fatigue affects attention, memory, inhibitions, and reaction time, is to recognize the need for rest and relaxation as well as for stimulation and variation.

FEAR. Basically, fear is the reaction of an individual to a situation for which he has no ready and adequate response. Recent studies have shown that the definite behavior pattern which we know as fear probably is

not present at birth. However, the newborn infant does show startle and withdrawal responses (often accompanied by crying) to strong, sudden, or unexpected stimuli, such as loud sounds, loss of support, etc. Very early in life this generalized reaction, with the combined effects of learning and maturation, becomes crystalized into the behavior we call fear.

Fears of specific objects or situations are not innate but are the result of conditioning and learning. Thus, if a sudden loud noise accompanies the presentation of a toy to an infant, the fear evoked by the sound becomes associated with the toy, and the child will show fear reactions to it when it is presented without the noise. This conditioning process operates both in childhood and adulthood; many specific fears can thus be accounted for. Contrary to popular opinion, a child does not outgrow fears, but their number and variety increase with age. It has been shown, too, that parental attitudes are a factor in the development of fear, children tending to be more fearful if their parents are fearful.

Worry may be considered as a more generalized type of fear which affects a larger segment of experience. It may result from the spread of unsolved specific fears, or may represent a general feeling of insecurity. For example, a frequent source of worry among children is parental discord, creating constant tension in the home, and undermining the feeling of security so essential to a child's emotional health. Unsatisfactory school adjustment, also, is a prolific source of worry to children, caused by an overemphasis on artificial standards of success, such as marks and grades, and the constant threat of failure. There is a positive relationship, too, between physical condition and worry, those children and adults who are in poor health showing many more fears and worries.

Fear responses once served a valuable purpose in the preservation of the individual. The physiological changes accompanying the so-called "emergency emotions" of fear and anger have the general effect of increasing bodily energy, so that one may cope better with the dangerous situation either through flight or combat. Intense fear, however, may have an inhibiting or blocking effect which prevents the person from making any form of response. Since, in our civilized society,

the need for physical protection has diminished greatly, the inhibiting effects of fear seem to be somewhat more frequent, and are usually referred to as emotional blocking. Illustrations of such blocking are to be seen in the child who is so afraid that he cannot recite in school. Stammering is perhaps the best known symptom of emotional blocking, a large proportion of it being attributable to fear. Fear of the teacher or of failure may also be so acute as to lead the child to adopt a listless and seemingly indifferent attitude, which scolding or punishment serve only to aggravate.

The success of the methods used in dealing with fears depends upon the type of situation involved, the child, and the adult employing the methods. Diverting the child's attention from the object or event feared has been shown to be of only temporary value. Neither are fears eliminated by forcing the child to meet a feared situation. Other methods of doubtful value are: showing by personal example that there is nothing to fear, ridiculing the child, or trying to talk him out of his fear. A fear may be dissipated by having the child join a group who are unafraid, but there is a possibility, also, of the other children imitating his fear. The development of new skills may sometimes overcome a fear, e.g., giving a boy boxing lessons so that he can defend himself more adequately. Probably the most effective method, however, is to associate the feared object or situation with pleasantness and success. Thus, fear of animals can be overcome by associating them with some pleasurable experience. As a means of securing obedience, fear is undesirable because it persists beyond the occasion for which it was used. Not all fears can be prevented, nor would this be desirable, as some are essential for the child's protection. Nevertheless, understanding and forethought by parents and teachers can prevent many unnecessary fears which interfere seriously with a child's efficiency and happiness. (See PHOBIA.)

FEDERAL ADVISORY BOARD FOR VOCATIONAL EDUCATION—See VOCATIONAL DIVISION OF THE UNITED STATES OFFICE OF EDUCATION.

FEDERAL AID. Federal aid to education has been a characteristic national policy from the earliest days of our national history. Without any attempt at this point to enter into the pros and cons of federal "control" as against federal "aid", some benefit may be derived from a factual legal discussion of the various forms of federal grants-in-aid to states for educational purposes. A grant-in-aid is a payment by the federal government to a state government to defray all or part of the cost of a governmental service administered by the state, generally but not necessarily subject to federal controls and conditions enforceable by withholding of future grant payments.

Even before the birth of the United States of America, while the states were still in a confederation, the Ordinance of 1785 directed that section number 16 of every township in the western territory should be forever reserved for the support of schools. Two years later the famous Northwest Ordinance of 1787 contained a declaration of policy in the following terms:

Religion, morality, and knowledge, being necessary to good government and happiness of mankind, schools and the means of education shall forever be encouraged.

When property in the Northwest territory was sold in 1787, lot 16 was set aside for the support of schools and not more than two entire townships were given for the purpose of a university. This policy was followed in practically all subsequent Congressional acts admitting states to the Union, starting as early as 1802 in the act admitting Ohio to statehood.

Agricultural College Acts — Land-Grant Colleges. The modern form of federal grant-in-aid to states for education dates from the Morrill Act of 1862 (Agricultural College Act of 1862, 12 STAT. 502, 7 U.S.C. 301-8). By this statute, Congress gave large portions of public land to the various states for the support of a college that would provide a "liberal and practical education of the industrial classes". The land was allocated

in proportion to the number of senators or representatives. Originally these grants were made as endowments, the income thereof to be used for the operation of a college of "agricultural and mechanic arts".

This act was a novel departure in at least two regards from the previous forms of federal aid to education. First, it provided assistance only for specialized forms of education, and secondly, it provided for differentiation among states as to need, however roughly ascertained.

The Second Morrill Act (Agricultural College Act of 1890, 26 STAT. 417, U.S.C. 322-8) was intended "for the more complete endowment and maintenance of colleges for the benefit of agriculture and the mechanic arts" established under the 1862 Act, through providing \$25,000 to each state that had established such an institution. The Nelson Amendment of 1907 increased these funds.

The last important Congressional action for land-grant colleges came in the Bankhead-Jones Act of 1935 (49 STAT. 436), which increased the annual appropriations to these colleges.

Vocational Education. Perhaps the most important general extension of federal grants-in-aid for education came with the Smith-Lever Act of 1914 (38 STAT. 372, 7 U.S.C. 341-8). Here Congress appropriated funds to be distributed among the states to foster agricultural extension instruction, and to disseminate information on subjects relating to agriculture and home economics among people not attending land-grant colleges, through coordination of the extension work of the land-grant colleges set up under the Morrill Acts and the United States Department of Agriculture. For the first time in federal grant-in-aid legislation, the Smith-Lever Act introduced the requirement of "matching" federal money with state money. This act also gave to the Federal government a greater degree of control than was found in earlier grants-in-aid.

In 1917, Congress passed the Smith-Hughes Act (39 STAT. 929, 20 U.S.C. 11-29) providing federal funds for distribution among the states to promote vocational education. These continuing annual appropriations were designed for the promotion of agriculture, trades, and industry, with a limited expenditure for home economics. The money was to

be used specifically for the training and salaries (to the extent of half their salary) of teachers, supervisors, and directors in schools lower than the college level. To administer the act there was set up the Federal Board for Vocational Education, since subsumed under the Federal Security Agency.

By 1928 public pressure for the extension of the work initiated under the Smith-Lever Act resulted in Congressional passage of the Capper-Ketcham Act (45 STAT. 711, 7 U.S.C. 343a), whereby additional funds were appropriated for co-operative extension work along the lines of the Smith-Lever Act, with the result that work in home economics and with youth in this field was greatly extended.

In 1929, Congress passed the George-Reed Act (45 STAT. 1151, 20 U.S.C. 15a-15c) providing supplemental appropriations to the Smith-Hughes Act, to be divided equally between vocational education in agriculture and home economics, excluding the trades and industry. By 1934, owing to the discontinuance of George-Reed funds, Congress adopted the George-Ellzey Act (48 STAT. 792, 20 U.S.C. 15d), appropriating a sum of \$3,000,000 for each of the next three years, to be divided equally among vocational education in agriculture, in trades and industries, and in home economics.

By 1936, with the discontinuance of the George-Ellzey Act fund, Congress adopted the George-Deen Act (49 STAT. 1488, 20 U.S.C. 15h-15p), which increased the appropriations available for the promotion of vocational education, and also introduced a new field for federal support, the distributive occupations. Funds were also provided for the training of teachers in agriculture, home economics, and trade and industrial subjects.

Concurrently with the two main trends of legislation providing grants-in-aid for education, there have been other forms of federal educational assistance to states. For example, one typical form appears in acts admitting New Mexico and Arizona to statehood in 1912, whereby a proportion of the income from national forests in those states was to be paid to the state for its common school fund.

Another form of educational grant-in-aid appears in the statute appropriating grant-in-aid funds to provide nautical instruction in educational institutions maintaining a marine

school or a nautical branch (36 STAT. 1353, 55 STAT. 607, 34 U.S.C. 1121-1130).

In 1933, the New Deal created still another type of educational grant to the states when it adopted the Civilian Conservation Corps Act (48 STAT. 22, 16 U.S.C. 585, as supplemented by 50 STAT. 319, 16 U.S.C. 584), which established the Civilian Conservation Corps (*q.v.*) and authorized cooperative agreements with states.

The latest form in which educational grants-in-aid have appeared is in the recent defense and war-time measures appropriating money for the training of defense workers and war production workers (First Supplemental Appropriation Act of Oct. 8, 1940, 54 STAT. 1033-5; National Defense Act of 1941; Labor-Federal Security Appropriation Acts of 1942 and 1943). In these latest types of federal grants, the philosophy established by the Morrill Act is carried on so that federal grants still are intended to promote a specific kind of educational activity.

Amount of Federal Aid. Federal funds for education are allotted to the states under three major categories: the regularly recurring appropriations for education, emergency allotments, and other funds used for education in certain states. During the year ending June 30, 1940, federal funds amounting to \$153,572,185 were distributed to the states (or to individual schools in them) for educational purposes. In addition, approximately \$3,500,000 was distributed from special revenue—such as national forest receipts—some or all of the funds being used for education in the states. The regularly recurring appropriations for that year (1939-40) amounted to \$55,117,370, or 34 per cent of the total; the remainder constituted appropriations for emergency purposes. The non-emergency funds were granted for five purposes: the increase of endowment and support of the land-grant institutions, agricultural experiment station work, agricultural extension service, vocational education, and vocational rehabilitation. The emergency funds were granted for three purposes: assistance for needy students, educational program of the Works Progress Administration, and school building construction. Table 1 shows the amount of emergency and non-emergency federal aid distributed in 1939-40 for each of the purposes enumerated.⁶

FEDERAL COMMUNICATIONS COMMISSION — FELLOWSHIP

Table 1
Amount of Federal Aid for Various Purposes

Purpose	Amount
Non-emergency Funds:	
Land-Grant Institutions	\$ 5,030,000
Agricultural Experiment Station	
Work	7,448,750
Agricultural Extension Service	18,584,642
Vocational Education	21,775,977
Vocational Rehabilitation	2,278,000
Emergency Funds:	
Assistance for Needy Students	28,088,592
Education Program of the W.P.A. .	28,243,054
School Building Construction	42,123,170
Total	\$153,572,185

Distribution of Federal Funds. Regular recurring non-emergency appropriations in 1939-40 for the five purposes listed above were allocated to the states as follows: \$10,696,332 in the form of flat grants, \$43,937,560 on the basis of population, and \$483,477 for special purposes. The emergency funds are allocated where needed in the form of flat grants to institutions, individuals, and states.

Approximately 47 per cent of all regular funds in 1939-40 was allocated through and expended under the Administration of the Division of Experiment Stations and Agricultural Extension Service of the United States Department of Agriculture. The remaining 53 per cent was administered through the Office of Education of the Federal Security Agency.⁶

Federal Aid and Control. Before the time of the Civil War, the policy of the Federal government was one of granting aid to the states without administering federal control. Educational policies were assumed to be a matter for the various states to determine. After the Civil War, however, the policy was changed by the addition of certain control features. Perhaps the greatest amount of federal control is exhibited in the administration of funds distributed for vocational education on the secondary school level. However, recent studies showing the need for increased federal aid for education have exhibited a trend on the part of the Federal government toward the return of its former policy of granting aid without control. (See also STATE AID; SUPPORT OF EDUCATION.)

FELLOWSHIP. A fellowship is usually an outright grant of money, given a person to allow him to do graduate or postgraduate work in America or abroad either at an institution designated in the grant or at an institution of the recipient's choice. Appointments to fellowships are made on the basis of the intellectual distinction attained or promised by the candidates, and on the basis of other personal qualifications. Considerable weight may be given to individual financial need when other factors seem equal. The award is usually granted for a minimum of one year.

Fellowships are of long standing in the universities of England, where the fellows have a responsibility in the administration of the institutions they attend. The first fellowship was given in the United States in 1865 at Yale University. Today numerous private foundations and leading industrial organizations also grant fellowships. (See also INTERNATIONAL SCHOLARSHIPS AND FELLOWSHIPS.)

FILIAL REGRESSION, LAW OF. The tendency for the average abilities and traits of siblings to be closer to the mean of the general population to which they belong than are the average abilities and traits of their parents. For example, the mean height of five siblings of very tall parents will tend to be less than that of the parents, and the mean height of children of two rather short parents will tend to be greater than that of the parents. This is related to the fact of imperfect correlation between parent and child in any trait. In spite of the "law," the human race is probably not becoming less variable, as one might at first be inclined to believe.

FINANCE, SCHOOL. *School finance* is one subdivision of *school administration* (*q.v.*). It is a broad field and enters into every phase of school administration. In many instances it is difficult to distinguish between a subject which might be labeled school finance and one which should be treated under school administration. School finance properly refers to the problems and practices related to the ways in which schools receive and expend the money designated for education and its functions.

Accounting. Since public education costs more than two billion dollars annually, it is obvious that adequate accounting systems are essential to its fiscal administration. In general, financial accounting has three purposes: It helps (a) to formulate policies for the administration of schools, (b) to determine the efficiency of the school system, and (c) to audit the school funds, thereby guaranteeing the honesty of the administration. However, public education has neglected the first two of these purposes and has placed major emphasis on the third.

Every state in the Union requires a periodic audit of school funds and most states require an audit at least every other year. The United States Office of Education and the National Education Association have been working since 1912 toward the general acceptance of a proposed uniform accounting system, which a number of states have already adopted. At the present time, however,

the public schools in general do not use uniform methods and terminology. Most school systems make provision for five ledger accounts: (1) Balance Sheet Accounts, (2) Appropriation Accounts, (3) Revenue Accounts, (4) Operating Accounts, (5) Fixed Charges.

The two major groups making audits are: (1) administrative, usually regular employees of the board of education; and (2) independent, the outside examiners of accounts.

In addition to the audit of bills before they are paid, and the occasional "surprise audit," the stated times for examinations of accounts are monthly, quarterly, semiannually, and annually.

Classified on the basis of the amount of detail and interpolation, the audit reports are: (1) condensed, as a terse recapitulation of the major receipts and expenditures; (2) detailed, as a meticulous record of all fiscal transactions; and (3) explained, as an interesting, narrative, pictorial report to the people on the stewardship of school funds.

There is a great need for improvement in the accounting systems of public schools. After satisfying the need for assuring honest administration of the funds, the next most important function of school accounting is to make possible accurate studies of unit costs, and in order to do this one must have comparable data. If the accounting systems of the schools concerned are not uniform, financial data are not comparable. This difficulty arises in large measure from the failure of school administrators to define their terminology and to agree upon uniform accounting methods.

The usual procedure for keeping school accounts is to have the clerk of the local district or the secretary of the board of education prepare and keep the records and reports for each school district. These records are then compiled by the county superintendent of schools who forwards them to the State Department of Education. The State Department audits the accounts and corrects any inaccuracies which it discovers.

One of the most neglected phases of school accounting is the so-called "internal school accounting." Most public school systems today conduct certain extracurricular activities (*q.v.*) which involve the raising and spending of funds. Although many schools handle hundreds of thousands of dollars annually,

FINANCE, SCHOOL

there is no adequate accounting system in operation in many school systems. Fortunately, however, there is a trend toward the adoption of adequate internal accounting machinery. In many of the more progressive schools a system is being set up which makes it possible for the students to cooperate in keeping the books of the school, thereby learning something of accounting and also participating in extracurricular activities. The plan generally recognized as superior is to have a bonded central treasurer responsible for all institutional funds. After adopting a budget, each club, class, or activity which raises and spends money within the school turns over to the central treasurer all funds received. An account is carried for each such group. All expenditures are paid by the central treasurer upon receipt of a properly signed voucher from the group's officers, and all payments are by check. Thus, although each group within a school may elect officers, keep books, and regulate its own activities, the group's funds are administered and safeguarded by a central treasurer and supervised by school officials.

Apportionment of school funds. Most of the states in the Union distribute funds to local school administrative units. In some states the counties also allocate money to local school districts. The Federal government, too, distributes funds for schools to the several states and, for a few particular purposes, to counties or other administrative units within states. This distribution or apportionment of funds constitutes an important phase of state school finance.

Historically, the apportionment of school funds by the Federal government to the states may be traced back to gifts of school land by the Federal government to the states for the purpose of establishing permanent school funds. To encourage public education, the Federal government, beginning in 1802, instituted a policy of granting to each state certain areas of land that could be sold; the proceeds went into a fund, the interest of which was to be distributed to the school districts of the state. Having begun this policy, the government increased the amounts of land and money apportioned to the states, until at the present time there are annual apportionments for particular purposes running into millions of dollars. (See **FEDERAL AID**.)

State apportionment of funds to local school districts became necessary when the state permanent funds were created. The laws which provide for state apportionment of school funds are complicated and widely different. In general, however, the states may be classified with respect to their apportionment laws as follows:

(1) States which maintain at state expense the minimum term in all local school districts, and then permit local districts to supplement the state minimum program. North Carolina is an example of this plan.

(2) States which, by means of an equalization fund and other basic state aids, equalize an educational program. The cost of this program has been determined in terms of some standard unit in all the districts of the state. The amount of support received by the district depends upon the relative wealth of the administrative unit. New York is an example of this type of apportionment plan.

(3) States which have a state equalization fund and equalize basic county aids so that educational opportunities throughout the state become approximately equal. South Carolina is an example of this plan.

(4) States in which all aid is apportioned on some standard measure with no attempt at equalization of the tax burdens, the amount of money distributed being sufficiently large to guarantee a reasonable minimum program. California is an example of this plan.

(5) States which apportion aid on one or more bases with no attempts at equalization.

Many different units are used as bases for apportionment, for example, census child, unit of average daily attendance, enrollment, number of teachers, number of classroom units, and weighted pupil units. (See **STATE AID**.)

Bonds. A school bond is an instrument issued by a corporate school administrative unit as an evidence of indebtedness. In general, bonds may be issued by "corporate" bodies. School districts are included in this definition, since a school district is classified legally as a "quasi-municipal corporation." A bond takes the form of a printed statement in which the issuer promises to pay within a stated time to the person legally owning the bond a stipulated sum of money at a fixed rate of interest, the interest to be paid periodically. A school bond is negotiable in char-

acter, transferable by endorsement or delivery and payable at some future date.

The issuance of bonds by school districts is controlled under the constitution and statutes of the states, and there is little uniformity in practice among the forty-eight states. The amount of indebtedness of this type which may be incurred by the school district is usually limited by law. In many of the states the limit is imposed in terms of the assessed or taxable valuation of the district. A typical percentage of assessed valuation is five per cent. The range of limit is from about two per cent to about fifteen per cent.

There may be said to be three principal types of bond issue—*straight term bonds*, *sinking fund bonds*, and *serial bonds*. The straight term bond issue is one which is floated for a period of years, the entire amount of the principal being paid at the end of the term. The sinking fund bond issue is a straight term bond, for which a sinking fund is created that will yield a sufficient amount of money to retire the bond when it becomes due. The serial bond issue is one which is retired by making payments at regular intervals; usually one or more of the individual bonds comes due each year throughout the entire term of the issue. The serial bond issue is generally regarded to be the best type of school bond issue and is the one most frequently used.

Bonds are issued in two principal forms, *registered bonds* and *coupon bonds*. Registered bonds are those in which the owners' names are registered with the issuer so that interest checks can be mailed. Coupon bonds are those to which are attached coupons providing for the payment of interest which may be clipped and redeemed at specified intervals.

In most states it is necessary for school officials to obtain by popular vote the permission of the electorate to issue bonds. In some states bond issues must be ratified by the state legislature or some other governmental agency. There is considerable variation in the procedures necessary to legalize a bond issue. In general, public school systems do not bond themselves for their operation; they more frequently use receipts from bond issues for construction of school build-

ings and purchase of school sites and equipment.

By the *pay-as-you-go plan*, capital outlay expenditures, as for school sites and buildings, are financed through the current school budget rather than through borrowing the money by bonding the district.

The controversy between the proponents of the bonding and of the pay-as-you-go plan is a perpetual one. The arguments in favor of the pay-as-you-go plan rest on the considerations that bonding may lead to extravagance in building, since people buy more critically when they are paying cash rather than paying in installments; and that bonding is more expensive ultimately because the interest as well as the principal payments must be made. In favor of the practice of paying for capital outlay expenditures by bonds is the fact that most small school districts could not obtain ready cash for a new building which is needed once in a generation. The pay-as-you-go plan actually may cost the taxpayer more if he has to borrow money at high interest rates in order to pay immediately his share of the building costs. The average annual rate of interest charged on school bonds sold in the month of November, 1942, was 2.16 per cent, which is much less than the taxpayer would have to pay if he were forced to borrow as an individual.

In the final analysis it is difficult to determine which method is better for a typical community, or for each taxpayer in that community. The nature of the times affects the problem. It is generally advisable to fight inflation by paying off debts, and it is sound sense to do as much pay-as-you-go business as possible in prosperous times, reserving borrowing power for periods of depression.

Selling bonds enables a district to spend large amounts of money at one time and to provide for the equitable distribution over a number of years of the costs involved to the taxpayers, so that persons benefiting from the expenditures for capital outlays may share equitably during their lifetime the costs involved.

Bonds are issued for a definite length of time, and the laws of the several states usually fix maximum periods for which bonds may be issued. The most frequent length of maximum period is twenty years, although some states permit bonds to run for as long

as fifty years. The average period of bond maturity is between twenty and thirty years.

Bonds are marketed by school districts in a number of ways, the two most commonly used being (a) selling them to the state or (b) selling them to private investment companies. Occasionally bonds are sold "over the counter," which means that they are sold at a fixed price to any person who cares to buy them directly from the school district. Probably the most satisfactory method for marketing school bonds is to sell them through investment brokers, who buy and sell securities of all kinds and bid for the purchase of the bonds, thereby assuring school districts a fair market price. Most states prohibit the sale of school bonds for less than their par value, although some permit it within certain prescribed limits.

Budget. A school or educational budget is a financial plan for a definite period based on careful estimates of receipts and expenditures for the operation of a school or school system. A budget is regarded by most school systems as a kind of contract entered into between the taxpayers and the public school officials.

A typical school budget is divided into three principal parts: (1) the *educational program*, a statement setting forth the general educational purposes and policies proposed in connection with the receiving and spending plan; (2) the *spending plan*, a detailed enumeration of the specific amounts of money to be expended for the several purposes proposed; and (3) the *financing plan*, detailing the proposed receipts as sources of revenue.

The interrelation of budgeting and accounting is evidenced in that the budget is prepared not for the school year but for the fiscal year, which is the legal division of the twelve months for the purpose of financial accounting. The most common date for the beginning of the fiscal year is July 1. As to length of time covered by the forecasts, the budgets are usually classified as (1) annual, (2) biennial, and (3) long-term. The typical public school budget is the annual one, covering the fiscal year. The budgets for some state institutions cover a two-year period. An increasing number of educational institutions are practicing long-term budgeting, by which the annual budget becomes part of a plan projected several years in advance. Long-

term budgeting is an attempt to substitute intelligent forecasts in place of the opportunism of a laissez-faire philosophy.

The typical annual budget is prepared by school officials for consideration by the Board of Education and other controlling agencies a few months in advance of the beginning of a fiscal year. When it is finally adopted, it serves as a basis for the tax levies to be imposed by taxing agencies for the support of public education in the particular district concerned. Authorities agree that preparation of the budget should be a cooperative enterprise by the superintendents of schools and his staff. In preparing the budget the school officials should keep in mind the long-time objectives of the school system, yet should be sure to make the document inclusive and detailed. It should be well proportioned and should provide sufficient revenue for financing the proposed program. Expenditures and revenues should be balanced. In presenting the budget the superintendent should be in a position to justify every item included and should be careful to give full explanation and full publicity not only to the Board of Education but also to the community. In administering the budget the superintendent should bear in mind the fact that the instrument is to be followed as closely as possible. There should be careful and systematic check on expenditures to be sure they have not exceeded the appropriations. All funds provided for in the budget should be systematically and regularly audited.

The budget making is, after the school staff has been selected, one of the most important single responsibilities of the superintendent. The way the budget is set up affects every part of the work of a school system. To a very considerable degree it influences the quality of instruction offered. Preparation of the budget, therefore, should be given careful study by the administrator, and the process of preparing it should be regarded as of utmost importance by all persons participating.

While there is considerable variation in the form of budgets, especially with respect to the division on receipts, there is reasonable uniformity in the budget headings for expenditures. Most budgets now list the following eight subdivisions: (1) general control, (2) instruction, (3) operation, (4) maintenance, (5) coordinate activities and auxiliary agen-

cies, (6) fixed charges, (7) debt service, (8) capital outlay.

Many states prescribe in their statutes the form budgets must take, and several state departments print blanks for distribution to the school system in the interest of uniform budgeting and accounting practices. The National Education Association and the United States Office of Education have given much stimulus to a movement toward uniformity in this connection.

Budgetary Procedure. Budgeting in public schools involves four major steps: (1) preparation, (2) presentation and adoption, (3) administration, and (4) appraisal.

(1) The preparation of a budget is a difficult and continuous task. In most districts the superintendent of schools prepares, with staff and board assistance, an educational program on which the budgeted estimates are to be based. Of specific aid in the preparation of the budget is a budgetary calendar which consists of a chronological schedule of dates with the specified budgetary procedures to be performed on or before the designated date.

(2) The tentative budget ought to be presented to the people as well as to the Board of Education. In fiscally dependent school districts the budget must be presented to some other reviewing body, such as the city council. In various local, state, and national surveys it has been found that many school district officials are guilty of a serious sin of omission in not recording in the board minute book the fact that a budget was presented and adopted in conformity with the existing laws. Too often tax fighters use the district's neglect as an excuse for cutting the levy for school purposes.

(3) After the budget has been adopted it should not be left to accumulate dust in a file but should be put to work. The budgeted estimates should be transferred to the accounting books where they serve as red warning signals at the head of the columns. In general the adoption of the budget by the board constitutes an authorization for the administrator to make the expenditures within the rules and regulations of the board. In public school administration, particularly in military and economic crises, numerous extrinsic factors beyond human control make the administration of the budget an extremely difficult task. Although the accumulative im-

pact of these fortuitous factors makes budgeting difficult, they also render it indispensable.

(4) A specific means for evaluating budgets and budgetary procedures is the school audit, which is a critical examination of the school accounts by competent persons, preferably trained in accountancy and education.

Capital Outlay. Money spent for anything (excluding supplies) that results in an increase in the total amount of property possessed, or in additional values, or in increased efficiency of property already owned, is referred to as *capital outlay*. In allocating expenditures care must be exercised not to confuse capital outlay with maintenance of plant. The major expenditures for capital outlay are purchase of land, improvement of new and old sites, erection of new structures, alterations of and additions to old buildings, and purchase of furniture and instructional apparatus for new and old buildings.

Planning Capital Outlay. Meticulous attention to details coupled with long-term forecasts should characterize the planning of capital outlay expenditures. There is more waste in planning and constructing school buildings than in any other school expenditure. Child accounting data, such as the continuing school census, and community surveys, such as spotting the homes of pupils on a map, furnish valuable information on which to project plans for school buildings.

Capital Outlay Budget. This is the section of the school budget containing the estimates of such proposed expenditures for permanent improvements as those indicated in the paragraph on *Capital Outlay*. The capital outlay budgets are usually of two types—the annual estimate, and the proposed long-term budget.

Cost of Public Education. How large an enterprise public education is in the United States is apparent from even a cursory survey of the number of pupils and teachers involved. In 1938 there were 221,660 public elementary schools, 25,467 public high schools, and 209 public junior colleges in the United States. This represents, in relation to 1936, an increase of 22 junior colleges, a decrease of 185 high schools, and a decrease of 10,514 elementary schools. The large decrease in elementary schools is due chiefly to the closing of one-teacher schools through consolidation. In 1938 the elemen-

FINANCE, SCHOOL

tary schools were staffed by 595,000 teachers, of whom 70,000 were men and 525,000 were women. The enrollment of pupils was 19,843,000. There were 282,000 high school teachers, consisting of 116,000 men and 166,000 women. High school students numbered 6,270,000. The average annual salary of all public school teachers, including principals and supervisors, was \$1,374.

In 1938, schools were in session, on the average, 174 days. Eighty-six per cent of the pupils enrolled were in attendance each day, making 149 days of schooling for the average pupil.

The properties of the public elementary and secondary schools of the nation were valued in 1938 at \$7,991,000,000. During the year 1937-38 they received a total income of \$2,493,000,000, of which 2 per cent came from federal funds, 30 per cent from state funds, 65 per cent from county, city, and district funds, and 3 per cent from nonpublic sources. The total expenditure was \$2,233,000,000, of which 10.7 per cent was expended for sites, buildings, and equipment, 58.6 per cent for salaries, and 30.7 per cent for all other items. This total represented a school cost of \$17.15 per capita of population, an expenditure of \$99.70 per pupil in average daily attendance, or 57 cents per pupil per day.

The public school population in 1938 represented 20 per cent of the total population of the nation. It was estimated that of every one thousand adults over 21 years of age 115 were high school graduates. A total of 16,350,000 high school graduates were living at that time. The number of persons graduated from high school for every one hundred 17-year-olds had risen from 6.4 in 1900, to 16.8 in 1920, to 29.1 in 1930, and to 45.6 in 1938. The increased holding power of the school in revealed further in another comparison. Of one thousand pupils in Grade V in 1930-31, 42 per cent were graduated from high school in 1938; the corresponding proportion for 1931 was only 27 per cent.

The amount spent per pupil in average daily attendance varies from state to state and is conditioned in many states by the number of Negro pupils in the schools. For instance, Mississippi spends approximately \$52 per white pupil in average daily attendance and about \$8, or approximately one-

seventh as much, per Negro pupil. New York State spends more than twenty times as much for every pupil as Mississippi spends for a Negro pupil.

It is interesting to note that the proportion of money which is being provided by the state governments for the support of schools has been steadily increasing. In 1926 the states contributed approximately \$134,000,000, or about 15 per cent of the total cost of public schools, while in 1940 the amount had increased to \$659,000,000, or more than 30 per cent. This is a desirable trend in that the larger the amount of state aid provided for school purposes, the higher the level of equalization of educational opportunity throughout the state.

The most complete and accurate data on the costs of education are compiled by the United States Office of Education, a subdivision of the Federal Security Agency. Each biennium this agency publishes a *Biennial Survey (q.v.)* containing extensive information on the expenditures of the various states and major cities by type and level of education and in terms of standardized unit measures.

Cost Accounting. This search for detailed fiscal information is designed to reveal the actual cost of each item or service rendered. Applied to education, cost accounting is the painstaking task of calculating the costs per unit, such as the money spent in heating a cubic foot of classroom space.

Data on costs are essential in the efficient management of schools. Cost finding is a difficult process in education because of the many variables. A committee of the Michigan Education Association listed forty-nine variables in comparative public school cost accounting, including types of heating systems, length of the school day, age and type of school buildings, amount of educational supplies furnished free to pupils, etc.

Costs have a qualitative as well as quantitative aspect. Usually the more money that is spent for instructional purposes the better the quality of teaching. Costs must be evaluated from the long-time as well as the immediate benefits to society.

In its publication, *Why Schools Cost More*, the Research Division of the National Education Association listed among the major reasons for the rise in school expenditures: the

decline in purchasing value of the dollar, the higher standards of education, and the increase in the size of the educational tasks assigned the schools.

Unit Costs. A unit cost is a specific instrument for measuring costs, as for example the expenditure per cubic foot for heating a school building. The measure used will depend largely upon the purpose for which it is intended. A unit such as a cubic foot may be satisfactory for measuring the cost of heating but not for instruction. The units selected to measure school costs should be easy to define and should have high validity and reliability. The highest possible degree of specificity should be used in defining the cost units.

Student Costs. One of the units frequently employed in cost accounting is the student or pupil. For example, in the United States in 1938 a total of \$2,233,110,054 was spent for educating 25,975,108 elementary and secondary school pupils in public schools. This amounted to an annual unit cost of \$85.97 per pupil enrolled. To the lay public the meaning of such a per capita cost is more readily understood than is that of some of the other measures. The unit may vary as to length of time covered, as per semester or year, and as to the kind of coverage, as cost per pupil for instruction or for transportation. The student cost data help to "personalize" accounting and form a helpful reportorial device.

Student Clock-Hour Cost. This represents the cost of one hour for each student. Class periods from 50 to 60 minutes are usually counted as a clock hour. If a history class of 30 students meets one hour per school day for a semester of 18 weeks, a total of 2,700 clock hours of instruction is represented. These costs are not used widely.

Student Credit-Hour Cost. This is more widely used than the student clock hour and is employed usually in higher education. It represents one student under instruction for a period of time for which one hour of credit is granted. If the history class mentioned in the preceding paragraph carries five hours of credit, then a total of 150 student credit hours is represented.

Student Subject Unit Cost. This is the cost for such an item as instruction or supplies or total costs for each student for each subject

he takes for a definite period of time, as the cost per student per year in mathematics or English. These costs are frequently used in budget building to determine the probable cost of instructional supplies.

Subject Costs. As indicated in the preceding paragraph the unit of measure may be based on the subject taught, such as mathematics or English. The specific unit may be the cost of a subject per pupil, as above, or the cost of teaching a subject irrespective of the number of pupils enrolled. While studies of subject costs are helpful to the school administrators, there is danger that the results may be overemphasized.

Grade Unit Cost. Here the yardstick used is designed to measure the cost of a particular grade, as seventh grade in comparison with twelfth grade. Usually the higher the grade on the academic ladder the greater the cost.

Textbook Cost. In calculating these costs the numerator is usually the cost of supplying school books to pupils and the denominator, the number of pupils. This unit is frequently employed in preparing budget estimates.

Student Accounting. (See PUPIL ACCOUNTING.)

Cost accounting in education is in its infancy. The need is for greater uniformity in accounting practices and for a greater number of cost accountants.

Debt. There are two principal types of indebtedness for educational purposes: (1) *bonded debt* (described earlier in this article), and (2) *warranted indebtedness*. Warranted indebtedness is that which is incurred through short-term loans, such as warrants, orders, and certificates. Usually it consists of outstanding checks, although in the case of school districts these checks are frequently called "warrants" and bear interest when they cannot be paid promptly. A warrant must be registered with the issuing agency and upon registration begins to bear interest at a prescribed rate. However, when the registered warrant is called for payment, interest ceases and the person who holds the warrant must cash it. Many states make legal provisions for the issuance of warrants in case of anticipation of the collection of funds, the terms and amounts of the warrants being fixed definitely by statute.

Most states prescribe a limit on school district indebtedness. Generally speaking, the

limit on bonded debt is usually about 5 per cent of the assessed valuation of the district. There is usually no legal limit on the amount of warranted indebtedness that may be incurred, although the credit of the district is weakened when excessive amounts of warranted indebtedness are incurred.

Debt service is the term used to describe funds allocated to the payment of interest or the repayment of debt, whether bonded or otherwise. The laws of most states prescribe that the school district must automatically set aside sufficient funds to meet the interest payments and repayments of principal on its debts. The levying and collection of taxes for the payment of this interest are usually automatic and constitute the first lien on the revenue of the school district.

In 1940, the amount of outstanding bonded indebtedness for public school purposes in the United States was approximately \$3,000,000,000, or about \$135 per pupil in average daily attendance in the public schools. The amount has remained fairly stable since about 1932. There is considerable variation by states, however. Complete data on school indebtedness by states may be obtained in the United States Office of Education's Biennial Surveys (*q.v.*).

Depository for School Funds. A depository is a bank or financial institution in which school funds are placed until expended. Among the common regulations concerning these depositories are the following: the safety of public funds for children should be placed beyond the reach of selfish individuals; private banks should not be approved as depositories for school funds; the selection of depositories should not be left with one individual; and, obviously, the depositories for school funds should be approved by the board of education.

Small school districts with funds amounting to less than \$5,000 are protected through the federal regulation insuring such deposits in approved banks. Some large districts demand collateral, such as federal, state, or local bonds, as security for public school funds.

Fiscal Year. A fiscal year is a financial year or that legal period of twelve months used for purposes of financial accounting. The most common dates for the school fiscal years are July 1 to June 30, used by approxi-

mately 60 per cent of all school districts. The next most common date is January 1 to December 31; about 15 per cent of all school districts use this period.

The period July 1 to June 30 is unquestionably the best to use for a school fiscal year. The beginning of that period comes during summer vacation, when schools are usually not in session, which is a convenient time to introduce a new accounting period. The state laws of most states provide that such a period shall be used for other governmental agencies, and the Federal government also uses this fiscal year.

Revolving Fund. Many school systems have a fund which is revolving in that the money is turned over repeatedly. For example, the board of education may establish a revolving fund for the purchase of school books to be resold to students. The term "advancements" is also used, since the money involved is not a true expenditure or receipt.

FIRE DRILL — See FIRE PROTECTION; SAFETY EDUCATION.

FIRE PROTECTION. Protecting the the lives of children and valuable school property against fire is the obligation of every person connected with the school. The board of education should provide fire-resistive buildings, should furnish fire-prevention

equipment and fireproof boiler rooms, stairways, and corridors, should make provision for proper care of rubbish, and should provide fire escapes, panic-proof doors, and sufficient corridors, stairs, and exits for rapid evacuation of the building. The board should also see that annual inspections are made by the fire marshal and should enforce strict rules and regulations concerning the disposal of trash, the care of inflammable materials, and the avoidance of other fire hazards.

The custodial staff must keep all fire-fighting apparatus in good condition. They must see that all door exits and fire escapes are in good working order, that all inflammable materials are stored outside of school buildings and protected against heat, that all closets are kept clean, and that all waste and trash are properly destroyed.

Most states require every school to hold a fire drill at least once each month or a specified number of times during the period in which the school is in session as a means of establishing a routine for the efficient and safe removal of pupils and teachers from the school building in the event of a fire or other emergency. To safeguard the health of the children, unnecessary exposure during extremely severe weather is prevented by holding fire drills frequently during the beginning of the school term and seldom, if at all, during the more inclement weather of the winter months.

An adequate fire drill program makes provisions for drills to be held at different hours of the day or at any times at which a fire might occur; for adequate instruction in the rules to be followed during fire drills or in the event of a fire; and for some means of evaluating the effectiveness of the fire drills in order that the highest degree of efficiency may be achieved. FISCAL YEAR—See FINANCE, SCHOOL.

FISHER, HERBERT, A. L. (1865-).

Herbert Fisher, the historian, is associated especially with the important education act passed by the British Parliament in August, 1917. At that time, he was Minister of Education in the World War I cabinet of Mr. Lloyd

George, following upon a career of active public and educational service. Passed by Parliament while Britain was at war, the Fisher Act was hailed at the time as an act to make England "a land fit for heroes."

Provisions of the Fisher Act: The general purpose of the act was the establishment of a national system of education, available to all capable of profiting thereby. Its essential features were the abolition of the half-time system, the extension of full-time compulsory school attendance to the age of fourteen without exceptions, the requirement of part-time attendance at continuation schools up to sixteen with provision to extend the requirement to eighteen, and the control of the employment of children. The act placed upon the county and county borough councils the duty of "providing for the progressive development and comprehensive organization of education" in their areas, with powers to provide nursery schools, to increase and extend existing provisions for school medical inspection and treatment, to aid research, and to provide maintenance allowances. With the requirement that each local authority prepare and draft schemes of education periodically, went the provision that no child capable of profiting by it should be deprived of an opportunity for further education.

The Fisher Act was the foundation on which the progress of education in England was built after 1918, despite the fact that "the appointed day" for putting the continuation school requirement into force was never fixed by the Board of Education and despite retrenchments due to economic conditions. World War II stimulated the proposal of plans for the further reconstruction of the educational system. (See ENGLAND AND WALES, EDUCATION IN.) I.L.K.

FITCHBURG PLAN. The credit for establishing the first cooperative industrial education course at the secondary school level in the United States goes to Fitchburg, Massachusetts. Daniel Simonds, president of the Simonds Manufacturing Company, was largely responsible for introducing coopera-

tive education in Fitchburg. The "Fitchburg Plan," an adaptation of the Cincinnati Plan (*q.v.*), was begun on August 1, 1908, and, although not now in operation, existed in Fitchburg for many decades. The Cincinnati Plan was worked out at the college level, whereas at Fitchburg adaptation was made to the requirements commonly met at the secondary school level. Cooperative education programs at the college level often call for periods of work in industry of a semester, or even a year, in length. In secondary schools the students rotate between employment and school on half-day, one-week, or two-week periods.

During the economic depression of the early nineteen thirties, many programs of cooperative education became inoperative. The programs were greatly reduced or completely abolished because jobs were scarce; the older workers with family responsibilities were retained whereas young learners were dismissed or put upon waiting lists. The cooperative education plan of combining schooling with work under actual employment conditions as carried on at Fitchburg, at York, Pennsylvania, and at many other places in the United States is an excellent plan, but one that requires constant attention, especially in years when unemployment is high. (See CO-OPERATIVE EDUCATION.) F.T.S.

FIVE FORMAL STEPS—See HERBART; INDUCTIVE METHOD.

FIXATIONS IN READING—See READING, EYE MOVEMENTS IN.

FLASH CARDS. Any piece of paper or cardboard with written or printed material that is to be recognized as soon as it is exposed or shown is called a *flash card*. *Flash* implies that the card is shown quickly, that is, for a very short time, and at the end of this interval the pupil or pupils should be able to give the response desired.

This device is used especially in the elementary grades, primarily to give training and drill in word recognition and the fundamental processes in arithmetic. In arithmetic,

for example, the combination 8 in addition is printed on the card which is flashed or shown for a few seconds, after which the pupil called upon is expected to give the sum

immediately. In reading, phrases and short sentences may be used on cards to give training in developing the recognition span. While no fixed limits can be set for the purposes of flash cards, the principal purpose is confined largely to drill in some fundamental process.

Flash cards are not used as widely today, even in the elementary schools, as formerly. The decreasing emphasis on the learning of unrelated factual material and the increasing attention to the child's ability to use his knowledge and his skills in the solution of problems necessarily reduces the importance of such a device as the flash card which stresses automatic responses rather than interpretation and application. Thus the lessened emphasis on the memorization of dates in history and of locational details in geography has made less frequent the use of flash cards in history and geography.

Where drill is necessary, the tendency is to conduct the drill in a meaningful setting wherever possible rather than by so artificial a means as flash cards. The teacher of reading prefers to have the child increase his reading vocabulary by extensive reading rather than by practising the recognition of unrelated words on flash cards. Similarly, the arithmetic teacher prefers to have his students use the arithmetic combinations meaningfully, as in the many situations arising from the conduct of a class drive for Red Cross funds, than by flash card drills on isolated combinations.

As a result of the decreased emphasis on flash cards, it is now possible for the teacher to reserve their use for those drill exercises for which they are particularly appropriate and to emphasize their usefulness for meeting the needs of individual children. (See DRILL; READING, REMEDIAL.) F.A.B.

FOLK HIGH SCHOOLS. The folk high school, the most distinctive educational institution of Denmark, represents one of the significant movements in adult education. It is a boarding school for adults from eighteen to twenty years of age, which offers a two-year course of study following the eight-year elementary school and the four-year continuation school. It is a people's high school, intended for all—rich and poor, urban and rural—although for the most part the students come from rural districts. It resents standardization and varies its program to meet the needs of its

pupils, but it is always religious in spirit and always aims at dignifying and vitalizing life. It has had great national influence, particularly in raising the standards of rural life and in improving the social, economic, and cultural conditions of the farming classes. The work of the school is closely related to the needs of the farm population, although the course of study is cultural rather than narrowly practical or vocational. The folk school has discarded the idea that one of the aims of education is higher salaries or more important positions; rather, it directs the thinking of its students toward the welfare of society, devotion to the Fatherland, and improvement of economic conditions in Denmark. The close relation of the folk schools to farm life has developed fellowship and common interest, and a recognition of mutual interdependence, on the part of the agricultural workers.

The folk high schools were established as a result of the educational thinking and activities of Kristen Kold, a leader in the movement to make Danish schools free and to make them a joyous and happy place for children, and Bishop Grundtvig, who is widely known as a Danish religious and educational leader. These schools are perhaps the strongest, the best organized and directed, and the most capably taught of all Danish schools; and they have had a world-wide influence upon the adult education movement. (See also DENMARK, EDUCATION IN; SWEDEN, EDUCATION IN.) E.H.W.

FOREIGN LANGUAGES, TEACHING OF — See CLASSICS, EDUCATION IN; LATIN, TEACHING OF; MODERN FOREIGN LANGUAGES, TEACHING OF.

FORESTRY EDUCATION. Professional education in forestry was first undertaken as a four-year undergraduate curriculum at Cornell University in 1898. This School was discontinued in 1903, revived in 1911, and finally closed in 1940. Postgraduate instruction was instituted at Yale University in 1900

and has been continuous since that date. The University of Maine, University of Michigan, and Michigan State College began undergraduate instruction in 1902, followed by Iowa State College and Harvard University in 1903. University of Minnesota in 1904, and Pennsylvania State Forest Academy, Mont Alto, in 1905. In the South, the University of Georgia established a school of forestry in 1905, while on the Pacific Coast the University of Washington was the pioneer, in 1907. With the exception of Harvard, whose undergraduate instruction was discontinued and placed on a postgraduate and research basis in 1914, Yale University, which is wholly postgraduate, and Duke University, which established a postgraduate School of Forestry in 1938, the curricula in professional forestry offered in existing schools are for undergraduates, although postgraduate instruction leading to the degree of Master of Forestry (M.F.) is also given at 13 other institutions and the degree of Ph.D. was awarded at eight schools in 1941. Including 1941, the number of undergraduate degrees awarded in professional forestry is 11,013, and Master's degree 1,996.

In the first two decades of forestry education, the curricula were patterned somewhat after those of European schools of forestry and considerable material was drawn from German, French, and Scandinavian sources. Education was aimed at preparing students for employment with the federal agencies, chiefly the U. S. Forest Service, later for numerous state forestry departments, and not until much later for employment by private industry, though a few pioneers entered this field early in the century. Since field conditions on these public forests did not lend themselves to intensive silvicultural practice but demanded practical training in fire fighting, construction of improvements, the supervision of logging on timber sales, and the acquisition on the open market of vast areas of forest land by purchase from private owners, these requirements rapidly modified the character of instruction given in the schools some of which moved rather far towards the vocational side of training. With the advent of interest in forestry practice by large private timberland owners, which took form after 1915 and was greatly stimulated by the N.R.A. legislation during the depression of

1932 requiring minimum silvicultural requirements in woods operations, pressure arose to give to instruction in forestry a more practical business basis, which would fit the graduate to cope with problems of accounting, marketing, and organization of woods and mill operations. These trends towards vocational and business training were offset, first, by the development of a large field of experimental research in the Forest Service and in state organizations which laid emphasis on basic sciences and intensive training in ecology, silvics, soils, higher mathematics and statistical methods, bearing on the problem of reproducing and growing forests, and second, by a parallel development in the field of wood technology and products, including chemistry, paper making, and many lines of fabrication of new products.

Previous to 1930, efforts had been made by professional schools to agree upon subjects which should be included in a professional four-year undergraduate curriculum in forestry, and most of the 20 institutions giving such instruction in that year followed rather closely the pattern advocated. Differentiation had already set in at certain institutions, notably the New York State College of Forestry at Syracuse, which offered curricula with separate majors in forest management, game management, forest entomology and pathology, landscape and park engineering, forest recreation, arboriculture, technical properties of wood, conversion and distribution, and pulp paper manufacture. A cleavage developed in several institutions between curricula centering on land management, and those dealing with the logging, manufacture and utilization of wood and its products, and this differentiation is extending into several institutions. A further cleavage arises between curricula dealing with either or both of the above branches of forestry and those treating of wildlife management and range management which during the decade of 1931-40 became well organized and prominent in schools of forestry, giving rise to some confusion as to the limitations of a professional forestry curriculum.

In 1930 the Society of American Foresters received a grant of \$30,000 from the Carnegie Corporation for a critical study of Forest Education, which was conducted by Dean

Henry S. Graves of Yale and Prof. C. H. Guise of Cornell, resulting in the publication of *Forest Education* (Yale University Press, 1932), which defined the standards which would be reached by existing institutions.

In 1935 the Society of American Foresters undertook a critical analysis of all existing schools, and, complying with its Constitution, gave accredited status to 14 institutions. As the result of later compliance with standards set, six additional schools were accredited as giving adequate professional forestry instruction. In 1941-42 a revision of the status of forestry schools was initiated, in which 24 institutions were inspected. H.H.C.

FORGETTING—See MEMORY.

FORMAL DISCIPLINE. Etymologically, to discipline (Latin *discere*) means to teach. Ordinarily, however, it means something more; it means to teach according to some particular rule or pattern. Since order or pattern is the very essence of form, the phrase, formal discipline, is somewhat redundant. The important respect in which "formal" modifies "discipline" becomes more clear when the particular pattern to which teaching is to conform is indicated. Conventionally, it is the form of the mind rather than the content of the subject matter which is to guide the teacher in his efforts. He is to provide exercise in such traits as reason, memory, imagination, will, and the like rather than mastery of such subjects as language, science, history, and mathematics.

The emphasis on the form rather than the content of learning has been variously stated theoretically. Since the content of education appears to have no limit in amount and variety, it would seem an economy of effort to direct the major attention of education, not toward the endless task of mastering content, but toward training in those forms of thought and action in which all learning content is cast. But formal discipline finds its chief support in the theory that practice in such traits as reasoning or memorizing with one type of subject matter will improve these mental processes in general and therefore be available in other subject matter fields as well. Furthermore, where reason, memory, imagination, and will are thought to be faculties of the mind, faculty psychology itself lends reinforcement to the theory that educa-

tion should be primarily concerned with their exercise.

So stated the theory of formal discipline extends far back into antiquity. It has been asserted most prominently and frequently in periods of cultural lag. Thus, when subjects originally introduced into the curriculum for utilitarian purposes, continue to be studied in a later period when their obvious usefulness has disappeared, there is a strong tendency to justify this persistence in terms of the formal discipline they afford. Indeed, some subjects, notably Latin and mathematics, have come to be noted in the course of educational history as the disciplinary subjects par excellence.

It was not till the end of the nineteenth and the early part of the twentieth century that the theory of formal discipline was scientifically investigated. A large variety of experiments was then performed to test it as a theory of "transfer". A summary of the results of these studies would seem to indicate that (1) the casual transfer of improvement from exercise in one field to that in another is not nearly so great as had been claimed nor does the improvement transfer equally and uniformly (2) the transfer may be negative as well as positive, that is, instead of improving exercise in the second field, it may actually hinder it (3) to the extent that transfer does occur, it is a transfer, not of the power to reason, memorize and the like, but of facts and information, or, skills, procedures, and attitudes which were identical in the two opportunities for exercise, and (4) transfer usually takes place most effectively when it is one of the objectives of both the teacher and the learner. (See also TRANSFER OF LEARNING.)

FOUNDATIONS OF EDUCATION.

The term *foundations of education* has come rather rapidly into the vocabulary of teacher education during the last decade or two and perhaps most often refers to the common or basic preparation that all prospective educators should have despite their respective specialties of subject matter or educational func-

tion. In the past, such courses have sometimes been known simply as "education" courses to distinguish them from the usual academic subjects in colleges or teachers colleges. They have also been distinguished from "methods" courses in special fields by virtue of their attention to the basic principles upon which practice rests. In general, the courses in the foundations of education have included history of education, philosophy or principles of education, educational psychology, educational sociology, educational economics, comparative education, and similar courses.

In more recent times, and principally since the depression days of the early 1930's, some far-reaching changes have begun to appear in the foundations of education in some colleges and universities. The impact of the first World War, the depression, and another war has made educators realize more fully that they must study and understand thoroughly the relations between education and the surrounding culture. The original principle was maintained that this was a task that should be common to all educators, no matter what their subject field, function, or level at which they worked, but it was now evident that the task of understanding the relation of school and society could not be done adequately in separate, discrete courses in education.

Thus a second principle was emphasized, namely, that a more coordinated and integrated course in the foundations of education should be provided as a basic course in the preparation of teachers and administrators. This meant that such a course would deal with the fundamental social and cultural problems of our time by drawing upon history, philosophy, psychology, sociology, government, economics, anthropology, and the other arts and sciences, as they were needed.

A third principle of organization that often appeared was the insistence that the foundations of education are practical as well as theoretical. Their main concern is to relate theory to practice, to improve educational practice by a broader understanding of the individual and the culture, and to develop appropriate beliefs and attitudes among teachers as the basis for improved practice.

A fourth principle that appeared and one that has sometimes evoked considerable opposition was that the purpose of educational

foundations courses is not only to help the student to examine and understand our culture in relation to education but also to help him make decisions as to the best action to take in matters involving social and educational policies. Whenever educators purposely enter the controversial areas of public decision, they are likely to be criticized not only by some of their colleagues but also by the public. But the proponents of the foundations approach have insisted that such problems must be dealt with and that sound points of view must be adopted, for the real concern of the study of education is the life of people as it is actually lived, not merely the structure of the formal school but the organization of the society in which the school exists.

The principal aim, then, of the course in foundations of education may be said to be a fundamental consideration of the nature and role of the organized educational enterprise in a democratic society. The scope of such a course is inevitably broad and is likely to include three major kinds of approach: The first is a study of the major social institutions that men live by, political, economic, and religious. Such a study may entail consideration of the origins and development of such concepts as democracy, liberalism, capitalism, industrialism, nationalism, internationalism, science, religion, and art in the various institutional forms in which they have been developed in America and in the rest of the world. A second approach is the study of the basic knowledge, beliefs, ideas, and attitudes that men live by. This may include a re-examination of our convictions about human nature, human destiny, self and personality, the learning process, thinking and intelligence, and science, art, and religion as ways of life. A third approach is the study of the effect such institutions and beliefs have had in the past and should have in the future upon the conduct of education, its aims, curriculum, methods, administration, organization, and the educational profession as a whole.

In general the foundations of education courses have tried to recognize and assimilate the best and most recent evidence appearing in the various fields of science, art, and social studies. Such an effort is difficult for any one instructor to undertake by himself and thus the practice of using panels for instruction has sometimes appeared. Panel teaching

makes it possible for representatives of different fields of scholarship to bring their special resources to bear upon the common problems, but the success of such cooperative teaching requires considerable and continuous planning by the panel members. (See PANEL DISCUSSION.)

Another procedure that sometimes accompanies the foundations course is the use of small discussion groups in which the students not only discuss the subjects for study but try to make decisions and arrive at mature points of view that will lead to action. In this way, practice in an essential phase of the democratic process goes hand in hand with the development of a working philosophy of life and education, a philosophy that will not only be satisfactory to the individual himself but will also have much in common with that of others. (See TEACHER EDUCATION.)

FOUNDATIONS, PHILANTHROPIC.

There is no standard title for corporate charitable funds. The first name is commonly *philanthropic*, *educational*, *charitable*, or *eleemosynary*; the last name is as commonly *foundation*, *fund*, *endowment*, *trust*, or *board*. They operate under individual charters, usually granted by state authority, or under the general charitable trust statutes of a state.

Philanthropic foundations are the product of a relatively mature capitalism and consequently, in the United States, are twentieth century creations. Some 600 foundations have been established in the United States but not more than 300 are active, and only 125 supply financial data which can be analyzed. According to most reliable estimates the total capital assets of American foundations approximate \$2,000,000,000. Twenty of the largest foundations have \$625,000,000 in assets; this is 87 per cent of the capital funds of the 125 foundations whose assets are definitely known.

It is as difficult adequately to characterize foundations by type or class as it is to list colleges, hospitals, newspapers, and similar social agencies. Foundations may be classified by field of major interest (e.g., education,

music, medicine), but such a category is not suited to the breadth of interest of the larger foundations. From the standpoint of an applicant for grants it is also important to know the geographical area served; some foundations operate in a single community, county, or state, while others are national or international. Students of foundations frequently classify them by the method of holding principal funds—some must hold the principal fund in perpetuity as endowment, in others it may be spent, and in still other foundations it must be spent in a specified number of years. Another way to classify foundations is by the source of the principal fund—if it comes from the gifts and bequests of many individuals the foundation is usually called a *community trust*.

The policies of a foundation are determined by a self-perpetuating board of trustees and carried into effect by an administrative staff. The organization and the quality of the personnel are very similar to those of privately controlled colleges and universities. A number of foundations act as their own operating agents and hence make no grants to outside agencies or persons. Other charitable trusts grant all their income to a single university or other operating agent. The largest group of foundations operates primarily through grants to outside independent agencies and persons, but there is a marked tendency toward restricting grants to a few agencies. For example, a diligent search discovered that only 453 of America's some 1500 colleges have ever received a foundation grant. The nine foundations that made approximately 90 per cent of the grants to colleges during the twentieth century concentrated 73 per cent in 20 institutions and scattered the other 27 per cent in 310 colleges.

Certain cultural areas are favored by foundations that make grants to outside agencies. Their interests are indicated by the proportion of \$528,420,034 which each of the following cultural areas received from 100 foundations in the decade 1921-30: education 43 per cent; health 33 per cent; social welfare 14.5 per cent; recreation 2.1 per cent; international relations 1.5 per cent; religion 1.4 per cent; law and government 1.3 per cent; miscellaneous and the cost of administration 3.2 per cent. Higher education projects re-

ceived three-fifths of the 43 per cent allocated to all types of education.

Higher education has been a highly favored field of foundation activity. The chief interest has always been in promoting research and implementing innovations. However, prior to World War I they did not promote many such activities because the public distrusted foundations, fearing they would come to control higher education in the fashion that business corporations dominated the economic life of the country. Foundations, therefore, began by helping selected colleges strengthen their general facilities through unrestricted grants to endowment and capital purposes. By 1920 the foundations had given \$220,000,000 to general endowment, so conditioned as to stimulate others to give an additional \$660,000,000; in the same period they had given, usually on condition that the recipient secure at least an equal sum from other sources, \$50,000,000 for capital outlay purposes.

Through grants for professors' pensions that required the college to meet specified standards, the Carnegie Foundation for the Advancement of Teaching provided a powerful incentive for improving teaching and research facilities. To achieve these ends the Carnegie Foundation has already given \$30,000,000 in pension grants and has assumed obligations which actuaries estimate will require \$69,000,000 to liquidate. Additional millions have been given for building, equipping, and endowing such research facilities as the Food Research Institute at Stanford University.

As another long range step in fostering research, the foundations have aided the training of personnel through grants for fellowships, scholarships, loan funds, and other forms of grants-in-aid. The aggregate of these grants within the United States has passed the \$30,000,000 mark, and they continue to supply approximately \$1,500,000 annually for this purpose. More foundations make grants for fellowships and student loans than for any other one purpose.

Research in professional fields first enlisted the aid of philanthropic foundations. Such research within the United States received \$214,000,000 during the first three decades of the twentieth century. Medical education received the lion's share, \$154,000,000; the

profession of teacher training or education *per se* received \$30,000,000; dental education \$10,000,000; legal education \$5,000,000; and the remainder went to such other professional fields as engineering, music, nursing, library science, forestry, and agriculture. The composite pattern of the grants to education is probably similar to that of the Carnegie Corporation where 48 per cent of the grants were for surveys and other practical studies aimed at immediate improvement, 24 per cent for research intended to advance educational knowledge, and 28 per cent to councils of learned societies and similar organizations to be used for the advancement and diffusion of education knowledge.

Grants for development and research in non-professional fields of higher education have practically all been given since 1920. In the decade 1921-30 grants aggregated \$65,000,000, increasing from \$2,800,000 in 1921 to \$10,400,000 in 1930. The shift in areas of interest during the decade is indicated by the fact that in 1921 the natural and physical sciences received \$1,300,000, the social sciences, \$182,000, the humanities \$46,000, while in 1930 the three areas received respectively \$3,800,000, \$5,300,000, and \$478,000. During the decade the natural and physical sciences received grants aggregating \$22,700,000, the social sciences \$27,400,000, and the humanities \$4,200,000.

The space allotted this article does not permit even a brief analysis of foundation interest in such marginal fields of higher education as photoplay appreciation and production, uses of radio in education, international peace, mental hygiene, housing and city planning projects, museum education, and public administration. Neither does it permit statements on foundation interests in research and the dissemination of knowledge in such fields as social work, adult education, child study and parent education, and other projects as near to the growing edge of American culture. For information on grants in these areas and for more detailed statements on the analyses, given items of the bibliography should be consulted, along with a study of the periodical reports of such foundations as the Bamberger Foundation, Buhl Foundation, Carnegie Corporation, Carnegie Endowment for International Peace, Carnegie Foundation for the Advancement of Teaching, Children's

Fund of Michigan, Commonwealth Fund, Duke Endowment, Falk Foundation, General Education Board, Guggenheim (J. S.) Memorial Foundation, Kellogg Foundation, Milbank Memorial Fund, New York Community Trust, Rackham Fund, Rockefeller Foundation, Rosenwald Fund, Russell Sage Foundation, Southern Education Foundation, and the Wieboldt Foundation. FRANCE, EDUCATION IN. Throughout the nineteenth century and up to the collapse of the country in 1940 the French system of education was marked by a high degree of centralization. Administrative control over most aspects of education was vested in the Ministry of Public Instruction, while the control of some aspects, such as vocational education, was left, until 1929, to other relevant Ministries. The principle of centralization—which was adopted during the Revolution as a means of breaking down regional loyalties, was continued by Napoleon, and was intensified during the nineteenth century—was preserved under the Third Republic as a safeguard against enemies from within and without, and to promote national solidarity. Thus the schools were secularized in opposition not to religion but to the power of religious organizations; schools were closed one day each week to enable pupils to receive religious instruction.

At the head of the system was the Minister of Public Instruction and Fine Arts (after 1932 the Minister of National Education and Fine Arts), appointed as a member of the Cabinet by the President from the dominant political party in power. He was responsible

for legislation, for the preparation and presentation of the budget, and for decrees and regulations. He acted as intermediary between the Ministry and Parliament and was in general charged with developing educational policy. The permanent conduct of educational affairs was in the hands of the permanent staff, distributed in various sections, and of bureaus devoted to special branches of the educational organization. To keep in touch with educational opinion in the field the Ministry had the advice of the Higher Council of Public Instruction (*Conseil Supérieur de l'Instruction Publique*), whose members were appointed by the President or elected by their own representative groups for each branch of education. The Council discussed and advised on courses of study, methods of instruction, examinations, administrative and disciplinary regulations, private schools, and textbooks. Recommendations for appointments and promotions were made by the Consultative Committee (*Comité Consultatif*) with ex-officio and elected members. Finally, the Ministry was assisted by twelve general inspectors, resident in Paris and making periodic visits to inspect their respective branches of specialization.

Thus the chief characteristics of the French system were wide powers entrusted to the Minister, employment of experts, clear definition of functions, and consultation with representatives of the teaching profession so that a certain uniformity was secured in all schools of similar grade through the prescription of curricula and courses of study, the supervision of all examinations, and the award of certificates and diplomas by the Ministry.

Hence the rest of the administrative organization consisted of a hierarchy of officials and councils with decreasing authority to carry out the laws, decrees, and regulations which issued from the Ministry. The academies, of which there were seventeen, were administrative areas established for educational purposes only. The chief administrative officer in each academy was the Rector of the university in its area, assisted by an academy council and inspectors and concerned mainly with the university and secondary and normal schools. Direct responsibility for primary education and normal schools was entrusted to the Prefect of each department, assisted

by a departmental council for education and academy and primary inspectors. In each commune responsibility for primary schools was entrusted to the mayor, assisted by a school committee (*commission scolaire*) and the local primary inspectors. All officials were directly responsible to the Ministry in Paris and none of the councils or committees had any right to initiative in the field of education, not even in schools that were built mainly with local funds.

The educational organization consisted of maternal schools (*écoles maternelles*) for children between the ages of two and six, primary schools (*écoles primaires élémentaires*) for pupils from six to fourteen, higher primary schools (*écoles primaires supérieures*) for selected pupils from twelve to sixteen, secondary schools (*lycées* and *collèges*), also for selected pupils from twelve to eighteen; and a great variety of trade, industrial, technical, and agricultural schools of various levels. At the top of the system were the seventeen universities and higher specialized schools at the post-secondary school level. Private schools existed but their establishment had to be approved by the Ministry; they had to meet the same standards as public schools, and be open to inspection. Elementary school teachers were trained in normal schools and secondary school teachers in the *École Normale Supérieure* or in the universities.

It is impossible within the compass of this article to discuss the features of these schools except to state that the French system and particularly the French concept of secondary education exercised a profound influence on education in many countries of the world. Its defects, however, began to be recognized during World War I, when a group of reformers, *Les Compagnons de l'Université Nouvelle*, initiated a movement for the common school system (*l'école unique*) with its demand for a common education for all at the elementary stage, increase of educational opportunities at the secondary stage, improvement of the standards of teacher preparation, and greater flexibility in the preparation of curricula and courses of study. In the period following World War I many of these proposals were put into effect. A common primary foundation was adopted, fees were abolished, and the number of scholarships

FRATERNITIES, PROFESSIONAL

were increased in secondary schools; all post-primary education began to be considered as a single unit; and in 1937 M. Jean Zay, the last Minister of Education of the Republic of France, initiated experiments with guidance (*classes d'orientation*) in a number of selected secondary schools.

After the collapse of France the opponents of the liberal movements in education, who were also in the main collaborationists with Nazi Germany, set aside all the reforms which had been achieved. Religious instruction was restored to the schools; equality of educational opportunity was abolished, and fees were reinstated in the secondary schools; the normal schools were closed as seed-beds of radicalism; physical training was given special attention; a youth organization somewhat on the Nazi model was created; and the last years of the primary schools were devoted to prevocational training, to be followed by vocational training, on the theory that work in itself is good for the masses and social stability can best be maintained by preventing mobility of any kind. The changes were based on an educational theory propounded by Marshal Pétain and General Weygand before the war broke out, with only one aspect missing—military training as the crown of the educational edifice.

founded in approximately 1819. Not much is known about how it came to be organized, but it was a Greek-letter fraternity in medicine at Transylvania University, Lexington, Kentucky, and was known as the Kappa Lambda Society of Aesculapius. Internal strife caused it to disband in 1835. At the present time there are professional fraternities in at least nine of the professions with well over 1,000 chapters in leading schools of the nation.²

Of the professional fraternities for men in the field of education, the following will serve as examples: Kappa Phi Kappa with 35 active chapters, 14 inactive chapters, 2 alumni chapters, and a membership of 10,073; Phi Delta Kappa with 50 campus chapters, 39 field chapters, and a total membership of 25,000; Phi Sigma Epsilon with 13 active chapters, no inactive chapters, and a membership of 2,800; Sigma Tau Gamma with 20 active chapters, 1 inactive chapter, and a membership of 5,000; Phi Lambda Chi with 3 active chapters, no inactive chapters, and a membership of 350; Zeta Sigma with 9 active chapters; and Phi Sigma Phi, a professional educational fraternity for men in teacher training institutions of college rank.¹

Kappa Delta Pi is an honor society in education for graduates and undergraduates of either sex. It has 122 active chapters and 3 alumni chapters.¹

Among professional education sororities Alpha Sigma Tau with 11 active chapters, 4 inactive chapters, 22 alumni chapters, and a membership of 2,800; Sigma Sigma Sigma with 32 active chapters, 13 inactive chapters, and a membership of 8,000; Delta Sigma Epsilon with 31 active chapters, 48 alumni chapters, and a total membership of 6,000; Alpha Sigma Alpha with 24 active chapters, 19 inactive chapters, 41 chartered alumni chapters, and a membership of 6,906; Pi Kappa Sigma with 28 active chapters, 11 inactive chapters, and a total membership of 7,500; Pi Delta Theta with 4 active chapters, and a membership of 1,000; Theta Sigma Upsilon with 15 active chapters and a membership of 1,993; Kappa Delta Epsilon with 10 active chapters; and Pi Lambda Theta with 37 active chapters and 14 alumni chapters.¹

FRATERNITIES, PROFESSIONAL.

A professional *fraternity* (many times called a *sorority*, if for women) differs from a general fraternity in that its members are selected from people with the same professional or vocational interest, while the general fraternity selects its members at large from the student body. The professional fraternity should also be distinguished from the scholarship-honor, or leadership-honor fraternities, usually thought of as societies. In the professional fraternities, more emphasis is placed on technical and professional efficiency and less interest on social projects. Many of the professional fraternities promote scholarships, loan funds, and grants for fellowships in graduate schools.

The first professional fraternity was

Fraternities (George Banta Publishing Co., Menasha, 1940).

FRENCH, TEACHING OF—See MODERN FOREIGN LANGUAGES, TEACHING OF.

FREQUENCY DISTRIBUTION. After tests have been administered, measurements made, or observations taken, there are usually so many scores that they must be organized to facilitate interpretation. In a *frequency distribution* the scores are listed in order of size in one column, and the total numbers of individuals who received each score appear in a corresponding column to the right. These scores are often spread over so wide a range that it is usually convenient to group them into classes. Thus, all scores between 140 and 149 may be included within one class, while the scores between 130 and 139 are included in the next lower class, etc. A typical frequency distribution is reproduced below. The letter *N* refers to the total number of scores in the distribution.

THE INTELLIGENCE QUOTIENTS OF SIXTH GRADE CHILDREN AT THE HILL SCHOOL

Intelligence Quotient	Number of Children
140-149	1
130-139	2
120-129	9
110-119	21
100-109	34
90-99	20
80-89	9
70-79	3
60-69	1

$N = 100$

The class interval, the range between the lowest and the highest scores in a class (in the statistical and not the school meaning of the word), should be of a size suitable for the data. It is usually desirable to select the size of the class interval so that there are between ten and twenty groupings for the distribution. In distributions of educational and psychological data, class intervals of 5 and 10 are the most common. However, any size of class interval may be used according to the nature of the distribution. The one important rule governing the use of the class interval in a frequency distribution is that

all the class intervals in a given distribution must be equal. If the distribution of teachers' salaries is summarized in a table with a class interval of \$200 (e.g., \$1,000-1,199; \$1,200-1,399; etc.) that interval must be kept equal throughout the distribution. It would therefore be wrong to record the higher salaries in such a class as \$3,000-3,500. Occasionally, when the extreme scores are not known, it is permissible to use for the first or last step interval such a group as "Above \$5,000—". When this is done, however, one must be certain to keep in mind this deviation from the usual practice, lest it be forgotten when such measures as the arithmetic mean are computed; otherwise the computation of such measures will be incorrect to a serious degree.

FREQUENCY POLYGON—See GRAPHIC METHODS.

FREQUENCY STUDY. A *frequency study* is a research study involving the determination of the frequency of occurrence or use of subsumed items in specified areas for purposes of curriculum construction or revision. For example, one study measured the extent to which adults used various mathematical facts and processes. Frequency studies are generally based upon the assumption that learners should be taught the kinds of things that they are most likely to use rather than the kinds of things that they are least likely to use, since it is manifestly impossible for the curriculum to include everything. Frequency studies may involve analyses of textbooks, large bodies of literature, activities, vocabulary, errors, records and report forms, motion pictures, etc. The general value of such studies has been questioned by some who believe that they offer little educational guidance. The major criticism advanced is that they indicate current status rather than desired or optimum status; and that importance cannot be inferred directly from frequency. If the results of these analyses are taken directly as objectives of education, then the criticism may be valid. But if frequency studies are regarded as suggestive guides in

the formulation of educational objectives, they may have significant value. The technique of the frequency study requires skillful application of the principles of sampling from the point of view of both the sources to be sampled and the proper sampling of each source.

The *error count* is a form of *frequency study* which is concerned not with frequency of use, but with frequency of errors made in usage. Thus, a teacher may tabulate the frequency with which various words are misspelled in the free writing done by her students. The object of this error count is to help indicate those items which are apparently least well learned and consequently most in need of remedial instruction. Of course, the importance of the specific items, as determined on some other basis, must be taken into account, since items which are missed with equal frequency are not necessarily equally significant. Error studies are particularly helpful in the "usage" fields, such as language, spelling, arithmetic, etc., where they may prove of considerable diagnostic value. However, typical error studies are subject to several limitations, among which the following may be noted: (1) they do not reveal why the errors are made, (2) they do not indicate the relative importance of the errors made, (3) they give no suggestion as to the psychology of learning for correcting the errors made, (4) they may tend to distort the picture by focusing attention upon a relatively narrow aspect of the learner's underdevelopment. Nevertheless, when properly used, and when interpreted within a larger sound philosophical framework, the error study constitutes a very useful diagnostic medium in education.

FRESH-AIR CLASSES—See OPEN AIR SCHOOL.

FRIENDS, EDUCATIONAL WORK OF THE SOCIETY OF. The educational work of the Society of Friends, or Quakers as they are commonly called, is as outstanding as their religious and philanthropic work. When, soon after the society was founded by George Fox in England, the Acts of Uniformity of 1662 brought persecution to all dissenters, the Friends kept open their meeting houses and established schools in defiance of the law. By 1671 there were fifteen Quaker

schools in operation. The Friends not only founded many types of schools of their own, but they attached themselves to every worthwhile educational development. In fact, Quaker influence gave impetus to most of the great English educational movements of the eighteenth and nineteenth centuries. The society provided free education to poor children of other creeds as well as to their own poor. It opened an adult school in Nottingham, which was the beginning of the great Quaker adult school movement, and inaugurated a plan for industrial education that involved teaching trades to all Quakers. The Lancasterian monitorial system, devised by Joseph Lancaster, who was himself a Quaker schoolmaster, owed its inception and early support to Friends. The society also opened Sunday schools, which were in reality mission schools for poor children, very few of whom were children of Friends. The widespread educational activities of the Society of Friends in England today include their support of secondary and higher schools, teacher-training schools, adult schools for men and women, mission schools in various lands, and great numbers of day and Sunday schools.

When the Quakers settled in America they brought with them a firm belief in the necessity of elementary education and of the mastery of a trade for all children, rich and poor. Since the Quaker religion made no provision for ministers with intellectual training beyond that of laymen, they established no colleges until the middle of the nineteenth century. Primary and secondary education were provided for amply by them, however, and it is in these fields that the Friends have had the greatest influence. In colonial days they established day schools—usually in close proximity to their meeting houses and often providing the only educational opportunity of the neighborhood—which were attended by the boys and girls of the locality. The most noted of the colonial schools was the Friends Public School of Philadelphia, chartered by William Penn in 1701. The central school, now the William Penn Charter School, had branches in various sections of the city, some for boys, some for girls; some free, and some charging tuition. The Yearly Meetings, the only ecclesiastical governing body of the Friends, were instrumental in establishing such schools in each of their regional juris-

FROEBEL, FRIEDRICH WILHELM

dictions. After the Revolution, they opened boarding schools that have become well known for their excellent educational standards.

The Friends in America have been as influential in backing educational movements as have those in England. It was through the American Friends that Joseph Lancaster came to America and introduced his monitorial system in the schools of Philadelphia and in other localities. In New York City the Friends started a free school for girls whose parents belonged to no religious denomination; they also supported the organization of the Free School Society, later the Public School Society, which paved the way for a free public school system in New York City. About 1850 the Quakers began to establish colleges. Haverford School became Haverford College, and Swarthmore and Bryn Mawr Colleges were opened—all near Philadelphia. The boarding school in North Carolina became Guilford College, and the one in Indiana, Earlham College. Other colleges were established in the West: Penn College in Iowa, Friends University in Kansas, Pacific College in Oregon, and Whittier College in California. Friends—particularly Moses Brown, Ezra Cornell, and John Hopkins—have been active in founding other institutions of higher education.

The educational principles of the Friends have always emphasized thoroughness in the fundamentals, honest and effective scholarship, and a severe discipline, leading to honest and simple living. Religious instruction in their schools has been along lines for which the Quakers are noted, namely, emphasis on high moral conduct, on peace and tolerance, and on practical philanthropy.

E.H.W.

FROEBEL, FRIEDRICH WILHELM (1782-1852). Froebel was born in the mountains of Thuringia in southern Germany. Froebel's interest in teaching was first aroused when in 1799, at the age of seventeen, he visited his brother who was studying medicine at the University of Jena. There he was greatly impressed with the intellectual activity centering about that institution and he awakened to an interest in teaching that never left him. He was invited to teach drawing in a Pestalozzian school at Frankfort, and when three years later he was engaged as a private

tutor to three children he spent most of time with his young charges at Pestalozzian institute at Yverdon, where he studied methods of the great reformer and became one of his most enthusiastic disciples.

At the age of twenty-four, after a careful study of the works of Rousseau, Basedow, Pestalozzi, Froebel opened an experimental school at Keilhau in his native Thuringia which was a pedagogical success but ended in financial failure. During the next few years he taught in various schools in Switzerland and in 1826 he published his great work, *Education of Man*, which contains the exposition of his educational philosophy.

The description of the School of Mother's Knee in the writings of Comenius confirmed his belief that the earliest years of childhood were the most important in education. In 1837 he opened his School for Little Children, the first kindergarten, in the mountain village of Blankenburg. The remainder of his life was spent in developing games, plays, and songs for the kindergarten, founding kindergartens, training kindergarten teachers, and elaborating on his methods.

The educational leaders of Germany at first opposed the kindergarten idea, but certain women, particularly Baroness Dülrow-Waltershausen, eventually won recognition for the kindergarten in Froebel's own land after his death. In the United States the first kindergarten was established by Mrs. Carl Schurz for German-speaking children in Watertown, Wisconsin. The first English-speaking kindergarten was started in Boston by Elizabeth Peabody, sister-in-law of Horace Mann; the first public kindergarten was opened by Susan Blow in St. Louis.

Froebelian Aims. According to Froebel the aim of education is the development of the inborn capacities and powers of the child. However, his conception of original nature was different from the pure naturalism of Rousseau. Froebel was the first real educational evolutionist. He believed that education is an essential element in cosmic evolution. Education to him was the process by which the race and the individual evolve to ever higher levels to the end of time.

Froebel insisted that there is one underlying power in the universe, the Absolute, manifesting itself as force in nature and as consciousness in man—an original, active,

ergizing, creative, intelligent, self-conscious source of all being. Creation is a continuous process of productive activity, and is the source of all things, including the child's nature, in this universal power which we call God. The forming crystal, the growing tree, the developing child—all reflect God's plan of creation, but under different manifestations. Therefore, any study of changes in the evolution of nature will throw light upon the nature of the development of man. All that man is ever to be lies hidden, however slightly revealed, in the nature of the child. Froebel looked upon man as a "human plant." The purpose of the educator is to control the growth of the child into a man, just as the purpose of the gardener is to control the growth of a plant to its full flowering and fruition. The aim of the teacher is to see to it that the development of the child is in accord with the original and logical course of human development. Failure in education consists of neglecting or preventing the development of certain sides of the child's nature, or of causing "the distortion of originally good human powers and tendencies by arbitrary and willful interference." If the child's nature has been marred, it must be redirected into the original course of development; if the child displays activities contrary to the true principle of growth, these must be recognized and corrected in order to keep the development progressing along the right lines. Thus, according to Froebel, education must be a controlled development by which the individual comes into realization of the life of the all-encompassing unity of which he is but a unit, a development by which his life broadens until it has related itself to nature, until it enters sympathetically into all the activities of society, until it enters into the achievements of the race and the aspirations of humanity. Education is but the realization in the individual of the evolutionary process at its highest stage. The work of the teacher is to bring about this unified evolutionary development.

Froebelian Method. Froebel considered education a process of creative self-development, which comes from what he called an "inner unfolding," and is brought about by means of the pupil's spontaneous self-activity. Froebel based his whole methodology on the principle of self-activity. He insisted that

only when a child is creating actively, only when he is "making the inner outer" as he put it, is he really developing. Like Pestalozzi, Froebel contended that the child must learn by doing, but where Pestalozzi depends upon natural objects from without to stimulate impressions, Froebel endeavors to draw out of the child, by means of self-prompted activities, every potentiality of his nature. Froebel did not believe that activities should result from outer stimulation or from an instinct to emulate but that they should come as a process of natural unfolding.

According to Froebel, educative activity is to take place only when the child is ready for it, when he has "certain felt need" for it; this readiness is a condition of his inner nature and not of curiosity, interest, or past experience. The teacher must see to it that the child has the opportunity to engage in the activity when the "budding point" is reached, when there is a felt need.

Froebel was the first educational thinker to perceive the significance of socialization as a basic principle of teaching. He maintained that the inner nature of the child impels him to co-operative activity with others. This was part of Froebel's central doctrine of unity in creative evolution. The "morning circle" in his kindergarten, where the teachers and all the children toed the circle and joined hands for song, prayer, and play, was a method of instilling a unity of feeling and purpose into the group. It was the duty of the school to make possible the expression of cooperative social activity so that the children would develop along lines of better forms of social living and thus play a part in the creative evolution of a better social order.

Froebelian Gift. Froebel's curriculum was an activity curriculum. His content was made up of all types of self-expression activities. Language was considered to be the earliest and most fundamental activity, which must accompany all other educational activities. He insisted that there must be a simultaneous development of language, song, gesture, and constructive activity. He included drawing and rhythm among the activities of the school, for he believed these to be nearly as essential to expression as language. Handwork was looked upon as an opportunity for expression, an aid to further impressions, a training of the mind through the hand. Na-

FUNCTIONAL DISORDER

ture study, instead of being a study of classified specimens, became the study of living and growing plants and animals.

Beyond everything else Froebel emphasized play as the most valuable form of self-expression. He was interested in its social and intellectual implications rather than in its health values. He developed and organized his play materials gradually and systematically, designating them by the terms "gifts" and "occupations." They were manufactured and sold especially for school purposes, and included, among other things, balls, spheres, cubes, cylinders, small blocks, sticks, and paper for folding—all designed to stimulate motor expression on the part of the child. He also developed many types of co-operative play and group games, minutely and systematically setting forth the songs and movements involved in each.

Even if we disregard Froebel's symbolism—that a spiritual meaning is intuitively grasped by the child from every "gift" and "occupation"—we must admit that he enriched our curriculum, especially at the early elementary level, with a vast amount of valuable educational material. E.H.W.

FUNCTIONAL DISORDER. The term *functional disorder* is commonly applied to an illness or maladjustment which has no organic basis, e.g., the absence of lesions or toxic damage, but is accounted for by faulty mental habits. This distinction, however, is being challenged by certain physicians who claim that it is fictitious and artificial, and that structure and function really are inseparable.

According to the older and more popular usage of the term, cases of headaches, paralyses, and sensory defects, where no structural damage is involved, would be classified as functional. These may include headaches due to emotional excitement or conflict; paralyses, such as those cured at shrines through emotional shock; and hysterical blindness and deafness. Such functional disorders increase

notably in time of war and during periods of economic depression when individuals are confronted with what they regard as intolerable situations and are unable to adjust normally to them. In all such instances the affliction is very real to the victim, and he cannot be accused of malingering. In the treatment of such individuals it is absolutely essential that the patient have faith in the therapeutic measures adopted. Generally, some sort of shock is given, and in most cases the "cure" is permanent. Although it seems rather paradoxical, those who have been cured from functional disorders rarely show any gratitude for their recovery. The following cases illustrate the manner in which functional disorders occur, as well as the characteristic type of treatment employed.

During an argument at the breakfast table a man threw a cup of hot coffee in his wife's face, and although no damage was done to her eyes, she insisted that she was blind. She was told by her physician that to restore her sight a minor operation would be necessary, and that severe burning sensations would be involved. A harmless but irritating solution was used, and she was told to open her eyes slowly and she would see. Her sight was restored by the burning sensation acting as the necessary mild shock, combined with her faith in the treatment.

A thirteen-year-old girl in a foster home developed functional deafness as the result of constant nagging and scoldings from her foster parents, and the tales of hardship and distress told by her real mother when she visited her. The deafness served to shut out these unpleasant experiences, and ceased when an adjustment was made.

The prevention of functional disorders depends upon the ability of the individual to face unpleasant situations squarely, and, wherever possible, upon removing or ameliorating sources of conflict in the environment. F.K.M.

FURNITURE, SCHOOL. It is now generally agreed that classroom furniture should be movable. This idea is in keeping with the trend from regimentation to individual freedom and self-direction; from stabilization to flexibility of arrangement; and from formality of class divisions to adaptability of grouping to meet specific needs.

The present tendency is to make the school as homelike and as comfortable as possible, and to encourage pupils to exercise initiative and individuality in the arrangement of furniture and the decoration of the schoolroom in keeping with their immediate programs. Today chairs and tables supplant the traditional school desk in most primary rooms, and a combination of tables, chairs, and adjustable desks is found in the intermediate grades of many modern schools. The trend toward flexibility of seating arrangement is extending into the junior and senior high schools. Tablet arm chairs and sometimes tables and chairs are being provided to replace the rigid fastened-to-the-floor desk of a few decades ago.

In the selection of desks and chairs, the goal is to afford as complete physical comfort as possible, keeping in mind the activities in connection with which the furniture will be used. In the selection of furniture, attention is given also to economy of equipment, economy of maintenance (including janitorial service), efficiency in administration, relationship to modern teaching methods, stimulation of study and learning conditions, conservation of vision and health, and opportunity for achieving the goals of modern school discipline. (See SEATING.) L.E.M. and M.F.S.

FUSION. *Fusion* refers to the bringing together of essential subject matter from different subjects or broad fields so that they

lose their original identity through a new form of organization. It is not a curriculum, but a method of selecting and organizing subject matter in broad fields, core curricula (*qq.v.*), or other forms of subjects curricula. There is no fusion in the experience curriculum (*q.v.*) since there is no prior body of essential subject matter which has to be reorganized. Both fusion and correlation (*q.v.*) stress basic subject matter. They differ in the degree to which they eliminate, reevaluate, and reorganize it. Fusion results in a more thorough reorganization which is achieved by regrouping around a large problem, generalization or theme. This transfers the center of relationship and offers a criterion by which to eliminate old and introduce new material. The original subject matter which contributes little to the development of the new center or organization is now considered non-essential. There is no fused curriculum, but there are fused courses. Parts of such subjects as history, geography, civics, economics, and sociology are organized around themes to become social studies. Parts of the subjects of biology, physics, chemistry, zoology, and physiology are combined into one area known as science studies. Most broad courses, such as general mathematics or general science, most survey courses, such as humanities or family life, and most unified studies and core courses are examples of fusion.

Fusion is frequently confused with integration (*q.v.*). There is fusion of subject matter but there is integration of experience or personality. Fusion is what an individual or group does to subject matter to make it more available for teaching and learning by someone else. Integration is the process by which an individual organizes his experiences into functional unity. Fusing the subject matter may be integrating for the adults who do it, but the effect may be quite disintegrating to the pupils who must learn it.

Every proposal for the reorganization of the curriculum within the subject outlook and framework utilizes fusion as a means to achieving its ends. Proposals for reorganization which stress the improvement of living of individuals and groups rarely utilize fusion since living is a qualitative self-motivated functional unity. Examples of fusion are so numerous and commonplace that they are generally accepted, yet are frequently un-

FUSION

recognized. Courses of study from city and state school systems are one of the best illustrative sources. (See CURRICULUM.) L.T.H.

G

GAMES, EDUCATIONAL. A game may be considered educational if its processes or outcomes contribute in some way to the educational growth of the individual. Toys and games which are participated in mainly for the purpose of recreation may be high in educational value, but often the term "educational games" refers to those schemes or devices used as a part of the regular program of school activities to furnish pupils with practice in the mastery or retention of certain facts or skills.

Most so-called educational games or drill-devices are variations of other games commonly played by children, with the content modified so that the child has to use curricular materials. Thus the primary grades child may try to toss a beanbag into one of the many holes cut into a piece of beaverboard. Each hole has a different score value and the children practice their addition combinations by adding their scores. Similarly there are hurdle races, baseball and basket ball games, tag, etc., which have been adapted from various common games.

The major value of most of these educational games is that they afford a pleasant means of practice on materials to be learned or retained. In the mastery of the fundamental combinations in arithmetic, the child needs a great deal of practice if these combinations are to be reduced to instantaneous, automatic associations which have permanence. These games, while furnishing the child with some amusement or fun, provide a means by which the child can practice the combinations with a degree of interest and persistence not commonly found in more traditional drill periods.

Aside from those who object to any form of "sugar-coating" in education, there are other educators who have criticized the use of educational games on different grounds. While they concede that these games may

have recreational value and offer a convenient means of relaxation from the tension or boredom of more traditional procedures, they believe that their educational values may become so incidental as to be lost sight of completely. On the other hand, it has been said that some teachers stress the educational values to so great an extent that these are called games as an expression of hope rather than as a description of children's reaction to them. So long as children have to do a division example, it makes little difference whether the teacher calls it an arithmetic practice period or a water polo game. Still others object to the ease with which teachers can resort to educational games as a means of evading their responsibility for finding intrinsic sources of motivation. It is significant, too, that educational games rarely provide for practice in the setting in which the materials will be used; the pupil in a language class playing "Who Is It?" says "Yes, it was I," and "No, it wasn't I," with little attention to the use of this expression in ordinary speech.

Since most games furnish but little repetition on specific items they are to be selected with care where drill is needed. If a game is to be of value in furnishing drill on specified items, it is necessary that the items on which the individual needs drill occur frequently enough in the game to furnish the repetition necessary to insure automatic response.

Educational games are more common in the elementary than in secondary schools, and more frequent in factual and skill subjects than in appreciational or interpretative subjects. How effective they will be depends on the teacher's skill in combining the appeal of a game with the educational value of offering opportunities for practicing a skill or an association needed by the individual pupils. (See DRILL; FROEBEL; PLAY; RECREATION; REVIEW.)

W.V.N.

GANG. A gang is a group of "teen age" boys which is usually formed spontaneously but is later united through conflict. It is characterized by the following types of behavior: meeting face to face, milling, movement through space as a unit, conflict, and planning. The result of this collective behavior is the development of tradition, unreflective internal structure, esprit de corps, solidarity morale, group awareness, and attachment to a local territory.

Gangs tend to become delinquent under conditions of community disorganization, and especially in border regions between well-established cultural groups. Membership of gangs is primarily determined by the mere fact of living in a particular area rather than by any innate characteristics of the individual boy. Emotionally unstable and intellectually incapable persons born into a socially poor environment most frequently constitute the membership of delinquent gangs. (See **JUVENILE DELINQUENTS.**) M.S.Q.

GARY PLAN. The plan of education instituted in the public schools of Gary, Indiana, in 1908 by William Wirt, then superintendent of schools, has been widely publicized, mainly for its unique plan of organization known as the Platoon Plan (*q.v.*), which provides as nearly as possible for the complete utilization of the school plant at all hours of the school day. Less conspicuous but equally important features of the Gary Plan, or the Wirt Plan as it might more appropriately have been called, include (1) an arrangement designed to improve articulation among the various levels of education within a local school system by housing all grades from kindergarten through high school in the same building under a single administrative principal; (2) a plan providing for opportunities in recreation, literature, and the arts for both children and adults by providing large playgrounds or parks adjacent to school buildings, as well as swimming pools, branch

public libraries, and art galleries in the public school buildings; (3) a plan for the year-round use of school buildings day and evenings, including Saturdays, for both children and adults; and (4) a plan of education known as the work-study-play plan (see **Platoon Plan**), which provides for the all-round development of children through a well-balanced and diversified curriculum.

GENERAL INDUSTRIAL SCHOOL.

In the technical sense, a general industrial school is that form of an all-day vocational industrial school in which students get instruction in elements of more than one trade—usually two related trades, such as machine shop practice and auto mechanics or carpentry and patternmaking.

To receive federal aid under the Smith-Hughes or George-Deen acts, such a school may be established in cities having a population of 25,000 or less, and may provide as little as 25 hours of instruction per week, instead of the 30 hours per week required as a minimum for unit trade schools. (See **INDUSTRIAL ARTS EDUCATION; UNIT TRADE SCHOOL.**) F.T.S.

GENERAL LANGUAGE. The 1934 report of the U. S. Office of Education listed 122 schools and 11,979 pupils enrolled in General Language, all but 678 pupils in the 7th and 8th grades, two-thirds in half-year courses. Taylor and Tharp found the course taught in 24 states in 1937, offered usually in the eighth grade, with a high degree of satisfaction expressed in a questionnaire answered by those who had taught the course.

The course takes several forms and combinations, and the textbook materials in print provide for these variations. It may be:

I. A study of the nature and origins of language as a form of communication, particularly of English in its formation and growth and enrichment by other languages and language forms.

II. A study of the cultures and civilizations of several foreign nations who have contributed to the American scene, with only enough language and music to provide emotional background and local color.

III. A series of sample lessons, ranging from three weeks to a semester, in the principal foreign languages taught in the schools to provide exploratory experiences in the actual language for prognosis of future study success; for orientation into the language of greatest interest and need; for a series of comparative language experiences to throw the mother tongue into relief and provide prospective to its structure; to provide basic phonetic principles to aid in reasonably accurate pronunciation of foreign names and words by announcers, singers, and the general public.

There are several books in print that attempt only Type I, although it has been said that such course work belongs properly to the English department, if teachers were adequately equipped and convinced of the validity of such activities. There have been several books published in English for Type II but in the main the "Foreign Cultures" course uses a wide range of library sources and audiovisual materials. By far the greatest number of books published for school use make some combination of all three types, usually Type I taking part of the book and the remaining part given to Types II and III in combination (that is, brief civilization sketches included in the exploratory lessons in each language). Although the work of Type II is essentially social science, it has been said that well trained foreign languages teachers are best equipped to direct the work and certainly they are the ones who must teach Type III.

Although the purpose of prognosis has been somewhat discredited (by Kaulfers and others), the value persists under proper circumstances, since there is ample evidence that adequate measurement of a sample experience long enough to reflect the activity in question is the most reliable prediction to success in a prolonged experience in the same activity, certainly better than measurements of general intelligence or of kindred activities. It is another question whether the returns justify the expense for this purpose other than to avoid some, but not all, loss and

frustration from course failures. The validity of the orientation-guidance feature is not questioned, but there is a grave difficulty in securing teachers broadly enough equipped to teach valid samplings of several languages, impartial enough not to proselyte for their favorite language, and clever enough to keep pupils from a now-I-know-it attitude or from feeling that a smattering of orientation is a substitute for real skills. Until such teachers can be trained, wise administrators should staff these courses by committees or by adjustment of teacher direction to avoid the dangers.

There is little doubt that the general language course is due to be greatly extended, especially in the 8th, 9th, and even 10th grades of high school. The pattern of "general education" is being set, the influence of the core curriculum is levelling subject-matter boundaries, and even the various foreign languages, highly competitive among themselves (especially modern versus ancient) are due to pool their interests in the early stages in order to provide longer continuance to the fewer pupils who start study to proceed later to established skills. GENERAL SCIENCE — See SCIENCE, TEACHING OF.

GENERAL SHOP. A general industrial arts shop, often called *general shop*, and sometimes, *laboratory of industries*, is a school shop in which several kinds of industrial arts education, such as work in wood, metal, electricity, and printing are carried on simultaneously under the direction of one teacher. In a general shop the equipment is usually grouped according to kind, and so

arranged that the instructor can readily supervise the whole shop. The general shop often includes a teacher's office, stockroom, finishing room, and a planning center in addition to the areas given over to various forms of shop instruction.

Since the general industrial arts shop does not emphasize vocational aspects, the general industrial arts shop must not be confused with the general industrial school, nor with general vocation education. (See **GENERAL INDUSTRIAL SCHOOL** and **VOCATIONAL EDUCATION**.)

GEOGRAPHY, TEACHING OF. In the past *geography* was in turn conceived as an explorational, descriptive, and utilitarian field. In the nineteenth century it developed an environmental point of view of the earth as related to humanity. Geography is now defined as an interpretive study or science of the interrelationships existing between the elements of the natural environment and the distribution and activities of mankind. Included among the natural elements are such factors as climate, topography, and various resources. Related human activities are economic responses, such as agricultural, extractive, manufacturing, and commercial enterprise; social responses, such as forms and distributions of living and culture; and political responses, including governmental arrangements. Geography thus draws upon and links the natural sciences, such as geology, astronomy, and biology—of which it is the mother science—and the social sciences, including anthropology, history, economics, and others.

Physical geography stresses the study of the earth's crust, the interrelations with it of the earth's atmosphere and water, and the consequent effects on human life. *Human geography* focuses attention on man-made features of the earth, dealing with man's ac-

tive modification of the earth's surface or his passive adaptation in failing to settle in some regions because of superior natural forces. Treating more specifically the livelihood of mankind and the geographical, historical, and political factors affecting its past and future course, *economic geography* is concerned with man's development of certain patterns in the production of the commercial commodities of the farm, ranch, forest, sea, and factory, and in their distribution, exchange, and consumption. One phase, *industrial geography*, describes the weight of natural and human factors in determining the location and development of the extractive and manufacturing industries. Another phase, *commercial geography*, studies the practice of exchange of surplus industrial commodities between regions, arising from differences in the character of peoples, in the types of resources available to them, and in their stages of industrial development. Consideration of available means of communication and world trade routes is included.

The emerging method of treatment of the geography of the world is the synthetic study of regions. The earth's surface is thought of as a mosaic of distinct regional landscapes, each representing a peculiar combination of natural and man-made features. The field of geography, under this concept, is the comparative study of the earth's regions, the definition of their limits, and the description of their peculiar "personality" characteristics and their interrelationships. The political and the natural regions, much used as bases of organization, are yielding to the human-use region because its basis is the uniformity of use while their unity is often either artificial or non-geographical. The corn region and the cotton belt are human use regions; the interior plains region of the United States, which includes the corn and cotton belt regions is itself a natural region. Study of human use or occupancy treats the relationship between man and his environment as activated primarily by man in his striving to mould nature's surfaces and products so as to fulfill his needs. Thus human geography attempts to furnish a much sought criterion as to the nature of geographical facts. It checks the excursion into the endless facts of highly specialized natural sciences that characterizes the natural regions approach, and

GEOGRAPHY, TEACHING OF

substitutes a definite, scientific field including the facts of human use of an area and its products, the reasons for such use, and the likelihood of man's continued use of it in that manner.

From an emphasis on sailor geography and factual geography of the natural environment, teaching has gradually shifted to a consideration of the modes of human life on the earth. Its general aim is to facilitate the adjustment of the future citizen to adequate social living by showing how and where men live, what they do, and why they live and work as they do. Associated with this aim is the development of a sympathetic understanding of other peoples' modes of life and a realization not only of man's dependence on earth conditions but also of the interdependence of peoples. With a view to the future, the teaching of geography also inculcates the desire for the better ultimate use of land and other natural resources. Among the values commonly ascribed to the study of geography are its training in the ability to obtain information by gaining familiarity with geographic tools; its training in observation, thinking, and proper habits of study; and its development of abiding interests and facility in following current affairs.

A variety of methods of teaching has been employed, which, though considered in turn, are not mutually exclusive. In the pre-geography stages, in home geography study, and in later study the observational method of getting geographical information at first hand is valuable. The imaginary journey method, though useful for lower grades in the study of modes of living and for upper grades as a method of review, is too sketchy for a full consideration of given regional units. The type method yields an intensive and richly detailed study of a people, industry, or region, and results in establishing a basis of future comparison. Though the topical method of considering a country or a continent in sequential serial order of topics such as location, size, shape, physical features, etc. has not recently been in good favor for presentation, it may be used advantageously within a problem or as a means of review. The use of stimulating problems, recognized by the pupils as challenges worth meeting and possible of solution on their level, characterizes

the problem method. Study of the problem, when it emerges from child experiences and yields new and valuable geographic information and insights, contributes strongly to an understanding of geographical relationships and principles. The same is true of the project and unit methods of teaching in which the field of research and experiencing by children is generally larger than in the problem study and is more likely to include other subject areas. Common to all the methods described are lesson types involving the inductive or deductive procedure, occasions for drill and review, class excursions, and devices for increased vitalization of learning, such as still and motion pictures, charts, maps, models, and various geographic apparatus.

Certain trends in geography teaching have been discernible. Study of local geography and psychological reorganization of material have been emphasized. The influence of nationally circulated textbooks has been weakened. Concerning the scope, basis of sequence, and grade placement of content there is not yet complete unanimity. An almost general preference for a one-cycle organization is evident. This, briefly, would include a study of a few representative peoples in contiguous regions extending from equator to poles, the continents considered in order of social significance and ease of comprehension, and a series of world views of our own and other countries in their commercial and political relations. The trend toward fusion, integration, or correlation of geography with other social studies and the spread of the activities program have emphasized the functional learning of geographical facts for desirable social use. The advocates of merging geography into the social science course stress uncompartmentalized units of experience as being more functional and more characteristic of learning in later life. The proponents of geography as a separate subject claim that social science courses omit much of natural science and fail to retain the necessary sequence in history. Others describe a desirable social science course as a skillfully wrought mosaic in which each of the components in turn becomes the core of a unit, with the others contributory. In social science, as in geography, the problems of scope, sequence, and grade placement have not been finally decided. (See MAPS, USE OF.) J.H.S.

GERMANY, EDUCATION IN. Under the Weimar Republic (1918-1933). The Weimar Republic was confronted with the problem of democratizing an educational system that had been built on authoritarian foundations in the spirit of devotion to the *Kaiser* and *Reich*. The schools had been administered by the states; local school inspection of the elementary school was left, in most part, to the clergy. The division into elementary, intermediate, and secondary (academic) schools with preparatory classes which alone gave access to the institutions of higher learning, followed class lines. Method and curriculum were most rigid on the elementary, less rigid on the secondary, and actually free on the university level. Political programs opposed to the established education; a strong school reform movement under idealistic slogans (*freedom, community, nation*), somewhat parallel to the bourgeois youth movement; and different types of experimental schools, grew steadily, but exerted little decisive influence before the first World War, and only a little more towards its end.

In the Republic all these new movements as well as the established traditions were backed up by various political parties, each violently opposed to the others, none strong enough to take a powerful lead. The conservative groups still advocated nationalism and military discipline; the liberal middle classes and the social democratic workers, freedom of individual development; the Catholic center, education in the denominational spirit; and the parties of the extreme left, later to crystallize into the Communist Party, stood for an education for class war.

As a way out of this ideological conflict an educational philosophy was offered by the disciples of Wilhelm Dilthey, prominent among whom were men like Eduard Spranger and Theodor Litt, and others close to them like the Prussian minister C. H. Becker, and Hans Richert, the author of the Prussian secondary school reform. They postulated a philosophy based on autonomous universal values as represented in the different aspects of objective culture. In the educational process each individual reconstructs these values according to his personal "structure". But the claim that this was the German educational philosophy was not accepted beyond the stratum of the cultured bourgeoisie which was powerful in the administration.

An official compromise was finally reached by the three parties of the Weimar coalition in the constitution. It reserved for the Reich the supreme right of legislation *only* with respect to the religious character of the schools. In spite of several attempts the law was never passed. Moreover, the constitution contained only certain general principles: the school systems were to offer equal opportunity to all; civic instruction and manual work was to be a part of every curriculum; there was to be a common elementary school for all denominations; preparatory classes (*Vorschulen*) to the secondary schools had to be abolished; teacher training was to be made academic; local school inspection was to be taken out of the hands of the clergy and to become the responsibility of civic officials. Only one *Reichs-law* was passed (in 1920, amended 1925) providing that all children except the very ablest should attend a common school (*Grundschule*) during the first four years of their school career.

Within these constitutional limitations, au-

GERMANY, EDUCATION IN

onomy remained in the hands of the states. As a result, the various school systems tended to reflect the political make-up of each state. In Prussia, for instance, the national-liberal ideals of Spranger—the integration of the curriculum around the homeland principle, and the introduction of the activity program, especially in the elementary school—prevailed in the school reform of 1923-24. The same principles were followed in the secondary school, and the traditional forms of *Gymnasium*, *Realgymnasium*, *Oberrealschule*, to which the new form of the *Deutsche Oberschule* with its concentration around German culture was added, were now interpreted as cultural types which were to be attended by students of the corresponding human types. Finally, a special academy for teachers was established, instead of a university department, which the teachers wanted. This was justified as being in line with the philosophy mentioned above, which classed the teacher as a special social type purportedly different from the university theoretician. More radical states like Thuringia, Saxony, Braunschweig, and Hamburg went further in the democratization of administration, in the organization of a unified school system, and in the reconstruction of curriculum and methods. In these states even the universities were reformed and their function extended to include teacher training. Bavaria, on the other hand, quickly became the most conservative state.

Alongside the official school reform there developed an unofficial one which strongly influenced it. This movement was due partly to the stimulus of the new political freedom, and partly to a continuation of pre-war school reform. It started with the community schools of Hamburg on the basis of romantic socialism, became more communistic in some experiments in public schools of Berlin, Northern and Central Germany, and the Rhineland, and finally turned democratic in some elementary and secondary public schools in Berlin, Hamburg, Dresden, Leipzig, and Magdeburg.

The depression led to new problems. On the one hand a contraction of educational opportunities became unavoidable and had destructive consequences for students and young teachers. On the other hand, strong political support was given to the idea of a ninth obligatory school year of a somewhat

vocational character and to labor camps as a cure for the economic and moral dangers of unemployment. But the republic fighting for its very existence had no longer the strength nor the calm to solve these problems.

Under the National Socialist Regime (1933-). When Hitler seized power, the Nazi theory of education had already been elaborated by men like Ernst Krieck and Alfred Baeumler. Based on the emotionalism of the expropriated lower middle classes, the first group of Hitler supporters, it violently opposed the "empty" humanism which formed the credo of the cultured and also underlay the longings of the working masses. The cultural value of the autonomous personality was replaced by the political: the soldier, the hero who lives, or better still, dies for the greater power and glory of the "superior" German race, and for its incarnation, the *Fuehrer*. Education must therefore give youth the consciousness of this mission and the vigor to fulfil it.

Educational authority, like all other authority, was vested in the *Fuehrer* alone. It is delegated to the Education Minister of the *Reich*, to the Youth Leader, and finally down to the school principal and the last group leader. It means *Gleichschaltung* of the states with the *Reich*, of the churches with the state, of the state finally with the party, of all former parties with the party, of all youth organizations with the Hitler Youth. (*Gleichschaltung*: officially—political coordination, actually a complete submersion in which the agencies to be "coordinated" lose their identity).

The democratic principles of school organization are replaced by the leadership principle with its ultimate aim, the selection of a Nazi elite. The process of educational nazification begins before birth with the marriage license for "racially pure" (*erbgesunde*) parents, continues in the homes for illegitimate "state children", in the three grades of the youth organization (*Pimpfe*, 4-10, *Jungvolk* 10-14, *Hitlerjugend* 14-18, and for girls the *Jungmaedel* 10-14, *Bund deutscher Maedel* 14-18), the *Landjahr* (work and life on farms for elementary school children), the Labor Service (compulsory since 1935), the military service, the elite schools (*National-politische Anstalten*) under state administration for selected secondary students, the *Hitlerschulen*

for essentially the same purpose under Hitler Youth administration, and the *Ordensburgen* for the training of the party élite of maturer age—25 years. The traditional schools fulfil a more auxiliary function. They are subject to interruption at any time for party activities. The secondary schools were cut from nine to eight years mainly to make way for the compulsory labor service. The prevailing type of secondary school is now the *Oberschule*. It provides two fields of specialization in the last three years, either language or science. For girls (whose "natural" vocation is to be mothers of soldiers) however, the second specialization is home economics. Of the other secondary schools only the humanistic *Gymnasium* still exists, but it is open to very few. The total number of students in the universities decreased from 95,807 in 1930-31 to 65,266 in 1937-38, of whom the percentage of women decreased from 18.5 to 12.5. The older and more famous universities now admit students on the basis of a selective quota. The various institutions for teacher training, once the pride of the Republic, were first transformed into *Hochschulen fuer Lehrerbildung* with the ideal of *Landverbundenheit*. The first year of the course of study became a year of work required of all candidates regardless of the field of specialization, something utterly new in German teacher training. But by 1941 academic teacher training was completely abandoned and reduced again to the status of the authoritarian seminar. The teachers gagged in the National Socialist *Lehrerbund* (membership is compulsory) can no longer oppose the frustration of their hundred year old aspirations for an academic teacher training.

Indoctrination and authoritarian discipline have replaced the activity school and its training for democracy. Absolute subordination to the supreme wisdom of the leaders is inculcated and, according to available sources, achieved.

The curriculum stresses physical prowess, history interpreted as Nazi mythology, geography as geopolitics, biology mainly as a study of heredity to justify the necessity for "racial purity", and home economics for women. The entire work of the schools is directed toward ultimate application in war. This is the new integration.

GESTALT PSYCHOLOGY—See PSYCHOLOGY, SCHOOLS OF.

GIFTED CHILDREN, EDUCATION OF. Gifted children are generally defined as those who are as superior intellectually to the ordinary run of children as the feeble-minded are intellectually inferior to the average. The IQ is used as an indicator of intellectual ability and, for gifted children, varies from approximately 130 to 135 and above. In organizing classes for gifted children, administrators often find it necessary to include some children with IQ's of 125, 120, or sometimes even lower. When a substantial number of pupils with IQ's under 120 are admitted to a special class, however, the group is rarely referred to as "gifted"; rather, some term implying lesser ability is used, such as "bright pupils" or "rapid learners".

The term "gifted" has supplanted such terms as "precocious," "prodigy," and "genius," which were used rather widely some years ago. Precocious referred to exceptionally early development and, popularly, implied that because development had been unusually rapid it would stop at an early age. Because of this erroneous conception of the development of exceptional ability, the term precocious virtually has disappeared from the educational literature. The term prodigy for many years suggested a child who was peculiar, unhealthy, even a freak, and is, for this reason, a term avoided in educational circles today.

The term genius has become so controversial in recent years that it is best used only with extreme caution. More than a quarter of a century ago Terman used the terms "genius" and "near genius" as a convenient classification for school children with IQ's above 140. Since 1930, psychologists and sociologists have been objecting to the prevailing use of such a definition of genius. An IQ of 180 or more is the point at which the

GIFTED CHILDREN, EDUCATION OF

term genius begins to apply, according to some. Others feel that the term is better reserved to apply to a person who *has* displayed some extraordinary and notable achievement. Thus, children of very high IQ's are only potential geniuses, especially since many of them never will make notable contributions to society because of circumstances or personal characteristics militating against such achievements.

Whether children with special aptitudes or talents, particularly the æsthetic talents, should be included among the gifted is still a controversial issue. Some hold that, since the school curriculum is organized so largely around intellectual activities, only talented children with superior intellectual abilities should be included among the gifted, especially if the gifted are in a segregated group. Others hold that any outstanding child, whether in intellectual, æsthetic, or even in mechanical areas, deserves special attention and should be included among the gifted since, all too often, only after children have been identified with a special group are they given the attention they warrant.

The approximate proportion of intellectually gifted children at various IQ levels to be found in the population at large is indicated in the table below, which was derived from data presented by Terman and Merrill in discussing the Revised Stanford-Binet Intelligence Scale.

IQ Revised S-B Intelligence Scale	Percentages Among Unselected Children
148 and above	0.1
145 " "	0.2
144 " "	0.3
140 " "	0.6
137 " "	1.0
133 " "	2.0
130 " "	3.0
128 " "	4.0
126 " "	5.0

Thus, if gifted children are defined as those having (Stanford-Binet) IQ's of 130 and above, this represents the highest three per cent of the generality of the population. If, on the other hand, the highest one per cent of a normal population is to indicate the gifted, an IQ comparable to the Stanford-Binet IQ of at least 137 is needed.

The term gifted, describing individual superior children or groups of superior children, is used only in professional discussions.

In discussions with parents or children it is essential that particular caution be manifested in the terminology used. Only in very rare instances should parents be told that their children are "intellectually gifted." As far as the children themselves are concerned, the use of any term which identifies them as being intellectually superior is objectionable.

Identification. The intellectually gifted are most accurately identified by means of individual intelligence tests administered by psychologists who are trained and experienced in the procedures of administering and interpreting such tests. In many school situations, however, the psychological service necessary in order to identify the intellectually gifted is inadequate for this purpose. The use of group intelligence tests therefore has gained considerable impetus (1) as a "screening" device for determining which children to recommend for individual testing, and (2) as one means in the actual identification of gifted children.

The upper level of the test is an important factor to consider in selecting a group test, or in interpreting its results. Some group intelligence tests do not measure a group of gifted pupils adequately because the "ceilings" of such tests are too low; that is, gifted pupils pass test questions at the highest levels and might pass questions at still higher levels if such questions were included. Some group tests are inadequate because they measure a limited area of intelligence, thus penalizing children whose abilities lie in directions other than those measured by a specific test. The use of two or three different types of group tests usually is recommended in order to counteract the disadvantage of any one.

Intelligence tests are based necessarily upon normal experiences of children. Young children, especially those with extraordinarily meager experiences, cannot respond adequately to such tests until such time as their experiences become broader and more normal. Thus a child who at an early age might not be identified as gifted may well be so identified in later school grades. Other gifted children who might not be identified as gifted are those who were seriously disturbed emotionally while being tested, or the occasional gifted child who is especially handicapped in reading and cannot, therefore, be measured by means of a test involving ability to read.

GIFTED CHILDREN, EDUCATION OF

It is important, therefore, that intelligence test results be supplemented by all other available data about each child for adequate identification of the gifted.

Measures for the identification of children with special abilities or talents require even more cautious interpretation than do intelligence tests. Some tests have been developed for the purpose of measuring certain limited aspects of special talents and must be supplemented by teacher and expert judgment regarding the child's achievement.

Characteristics. The popular conception of the gifted child as sickly, nervous, and maladjusted, caring only for books and nothing about the normal play and games of childhood, has long been prevalent. Quite the contrary has been found to be true. Gifted children as a group seem to have all the advantages over average children—home background, physical development, emotional adjustment, social characteristics and interests, character and personality characteristics, as well as intellectual and scholastic qualities.

Despite the superior behavior of gifted children as a group, certain of them do manifest conflicts and maladjustments. Such difficulties are especially significant because of the superior potentialities of these children. One condition which may result in disturbances among some gifted children, especially among those of very superior mental endowment, is a wide discrepancy between physical and mental development. The gifted child of a very high intelligence level may well become bored with—or be rejected by—playmates of his own age. No matter how he strives to play with others at or near his own age, other children may not share his interests, his vocabulary, or sometimes his desire to organize play activities along more intellectual channels. Playmates at his own mental level, on the other hand, are so much older and more developed physically that they, too, are very likely to reject him. Finding himself unpopular on the playground he may find escape in solitary activities, usually of an intellectual nature, or in activities involving only adults, thus setting himself even farther apart from other children. Unless such a child learns to adjust in play activities to others of lesser mental ability or else is provided associations with others of his own

mental caliber, emotional disturbances are inevitable.

Some maladjustments are actually encouraged by the school. A school program based on competitive academic activities will encourage those children who are superior in intellectual areas to place undue value on mental achievement, which might lead in the direction of one or another type of emotional stress. Some such children may become conceited and intolerant of others less able in academic areas. Other gifted children, however, actually may develop a feeling of inferiority because of ever-higher intellectual goals set by themselves and encouraged by the school.

Some of the intellectual qualities possessed to a greater degree by gifted children as a group than by other children are: superior powers of generalization, quicker insight into problems, greater independence in thinking, and superior imagination and creative originality with respect to intellectual tasks. Such generalizations as these, however, do not necessarily apply to all gifted children. Some children are very uneven in their intellectual abilities, displaying serious lacks in certain areas, probably because of factors in their educational and emotional histories which affected the development of interests, purposes of learning, and temperament. Some superior children, for example, rarely approach an intellectual task with "high mental energy" but are impatient with details and superficial with respect to locating and using information. Such children present a challenge to the alert teacher. Other children, instead of having wide and versatile interests, keen to approach new intellectual areas, are interested only in areas in which they already excel. An exploration into the emotional basis for such early specialization may be revealing.

Gifted children, moreover, are more likely than average children to achieve adult success—eminence, leadership, or financial achievement. The possession of superior intelligence is no guarantee of such success, however, since other factors, such as environmental conditions, sex, race, economic status, physical stamina, social adaptability, and motive or drive to accomplish, also play an important role.

Educational Adaptations. There is general

agreement that the curriculum for gifted children should involve enrichment, but procedures for providing such enrichment vary widely. Some involve enriching the curriculum for such children by progressing them rapidly through the grades. Others involve providing enrichment activities for the gifted children in regular classes. Still others involve segregating gifted children into special classes and providing a curriculum program specifically for the children in those classes.

The proponents of acceleration and rapid progress through the grades indicate that gifted children can shorten the period of preparation for the learned professions and thus achieve their professional degrees by the age of twenty-three or earlier. In order to prevent serious emotional maladjustments because of physical inferiority, especially in the later grades, a combination plan of special classes and rapid progress is proposed.

Enrichment activities in the regular classes may involve introducing supplementary activities, encouraging the gifted to participate in such activities, or they may imply an integrated curriculum along informal lines, including active participation of all pupils in classroom activities. Supplementary enrichment activities for gifted pupils may be provided during specific periods set aside each week, at any time during the school day when such children have completed their regular assignments, or during after-school hours. Examples of such activities are: special units involving research and reports to other pupils, hobby clubs, special service groups, school councils, and classes or clubs in aesthetics or dramatics.

In an integrated deformalized curriculum, situations are provided which encourage active participation of all pupils, the gifted included, in planning and conducting classroom activities. Creative work is encouraged and individual abilities are given opportunities to develop, taking into consideration, however, the needs of the group as a whole.

Special classes for gifted children have been organized in a number of communities throughout the country; the largest numbers of children organized into such classes are in New York City, Cleveland, and Los Angeles. The purposes generally stated for organizing such classes are to provide enrichment activities rather than acceleration, and to pro-

vide the children with the opportunity to work and to play with others of more nearly the same mental and chronological levels. Problems involved in organizing special classes include transporting of pupils from one school district to another; persuading heads of schools not having such classes to allow their gifted children to be transferred; keeping the class registers high enough without too great a chronological age range in such classes; providing these classes with adequate materials and equipment; providing the classes with sympathetic, intelligent, and well-informed teachers; providing normal and wholesome relationships between the pupils and teachers of these classes and the pupils and teachers of other classes in the school; and providing the children in these classes with experiences and interests in common with other children in the community. GOALS AND THE LEARNING PROCESS. The newer psychology sees goals as both cause and focus of endeavor: the individual acts in order to gain some end, something he desires or something he wishes to avoid. What he does is determined, in kind and degree, by the goal he sets before him. This is true not only of what are commonly referred to as problem-solving situations, but also of any situations involving conscious endeavor.

To examine this thesis in more detail: first, it is the pull of the goal on the individual which releases energy and arouses activity. Because he wishes the end, he initiates a series

GRADATION

of activities designed to achieve it—he thinks about means, he acts, he maneuvers to get what he wants. And he is activated to the degree to which he feels the goal is significant—to the degree to which he is “interested” in the outcome; for interest means exactly the pull of the goal on him. His persistence, too, is correlative with the importance he attaches to the goal. The individual, then, both undertakes activity and persists in it to the degree to which the goal, the end to be served, seems to him significant.

Second, the goal in mind causes the individual to act selectively and so to direct his efforts effectively. He pays attention to—notes, gives thought to, brings into focus of attention—what promises to further his enterprise. (The boy who is making a radio studies radio parts and instructions, not plants or poetry. He decides in terms of his goal what will constitute effective procedure. Without an end-in-view he cannot distinguish the relevant from the irrelevant; his activity is random, not directed. Without a clear goal he cannot discriminate, he cannot act intelligently.

Third, the goal provides a basis for evaluating achievement both throughout the process and in the end product. As the individual works he constantly asks, “Am I accomplishing what I wish? Does it meet my requirements?” To know his answer we must know his end-in-view. For example, does the boy wish to produce a really good radio or barely to satisfy a teacher requirement? The combination of elements which constitute his end-in-view will enter crucially into his process of evaluation as he proceeds and as he estimates the results.

Of the rich implications for education only one will be mentioned here: it must be apparent from the foregoing that it is the *learner's goals* (or absence of them) which determine both the quality and the extent of his efforts at learning. A goal which is merely or chiefly the teacher's does not generate dynamic or breed persistence or bring discriminating effort where it is needed—in the learner. Energy is accordingly well expended when it is directed toward stimulating interest in the learner, toward helping him clarify his aims and set up worthwhile goals; for it is *his* efforts which determine the learn-

ing and *his* aims and interest which determine the effectiveness of his effort. M.Y.O.

GRADATION. The arrangement of curriculum or teaching materials according to the grade or the maturity of learners, is referred to as gradation. Since curriculum materials range from the very easy to the very difficult, they should be taught in those grades where the pupils can assimilate them most economically. Gradation is the determining of where along the educational ladder various subject materials should be taught.

Several ways are utilized to grade materials. One is the judgment of teachers, administrators, and curriculum workers; this judgment is supposed to be based upon experience in teaching children. Another is the pupils' preferences—for example, their choice of poems and literary selections—based on their interests and satisfactions. A more recent method of gradation is by actually teaching a certain portion of a subject at different grade levels and then determining at what level is found the most understanding, the greatest economy of time, and the best pupil reaction. It has been demonstrated experimentally, for instance, that pupils learn best the division of decimals involving long division at the mental age level of about thirteen or fourteen, which would correspond to the seventh or eighth grade. As a result of research in gradation, many of the difficult parts of the curriculum have been located and shifted to higher grades. The economic, political, and financial treatments formerly found in seventh or eighth grade history have been moved to the senior high school level. The trend has been to shift from lower to higher levels rather than in the other direction.

Gradation also refers to the organization of materials and exercises within a topic and is an application of the principle *from simple to complex*. Much of the pupil's difficulty in grasping a concept or in mastering a process results from the haphazard order in which

his learning experiences occur. Inexperienced teachers often take too much for granted and fail to see that two examples which look alike and which seem to be on the same level of difficulty are in reality sometimes quite different. Thus the teacher who knows the basic similarities among all applications of percentage is surprised when a student who has learned to solve an interest problem does not know how to solve a discount problem based on the same principle. Similarly, the English teacher finds that his students can recognize and correct the error of dangling participles appearing in unrelated sentences listed in a grammar book, but that they cannot recognize this error in their free writing. The teacher who is sensitive to the need for gradation makes certain that his presentation of new material and of practice exercises confronts the child with only one new difficulty at a time. How fine the gradation should be depends on the nature of the material to be learned and on the mental level of the students.

Lack of necessary gradation both in curricular sequences and in topical teaching is a charge often made by critics of the experience curriculum and the activity program. [See **GRADE PLACEMENT (CURRICULUM)**].

F.A.B.

GRADE EQUIVALENT—See **NORMS**.

GRADE MEETING — See **TEACHERS' MEETINGS**.

GRADE NORMS—See **NORMS**.

GRADE PLACEMENT (CURRICULUM). As schools become increasingly concerned with promotion practices and the modification of the curriculum to meet the needs of specific groups and individuals, the problems of sequence and the grade placement of materials become correspondingly important. The sequence which is followed in any particular field may be one of the following:

1. Logical organization, such as the outline for a science course built on the logical basis.

2. The chronological age of pupils, such as a program of physical activities adapted to pupils of various ages.

3. Chronological order, such as the development of a history program beginning with

early times and extending to the present, organized with various periods allocated to succeeding grades.

4. The interests of pupils, such as the organization of units which attempt to take into consideration what is found to be dominant interests at various ages, for example, shopwork as an activity for the junior high school period.

5. The needs of pupils, in which units of health are organized around the problems of health faced by pupils at various ages.

6. Ease of mastery, in which the simpler principles are first presented, followed by more complex principles. Lack of experimentation in this field has prevented effective sequence in many areas.

7. Availability of materials. The lack of materials, such as suitable materials in reading and science, has prevented an organization of a sequence in these fields and has frequently confined the subject or activity to grades either below or above a point where it might otherwise be placed.

Few effective studies in the field of sequence have been carried out. It would appear that the following are essential in connection with the development of an effective program of curriculum development:

- a. Studies should be made as to the optimum placement of activities, experiences and content, in terms of the needs and interests of the individual, the ease of learning, and possible use.

- b. Other things being equal, experiences and skills should be learned at a point where they can be used as early as possible.

- c. Where principles and subject matter are concerned, the learning should be at such a point that it will facilitate, rather than retard, future learning.

- d. It should be recognized that in the many things which must be learned by children, attention should be paid to the problem of co-ordination and articulation, so that proper integration will go on in the child's mind.

- e. The fact that a principle or skill can be learned at a particular level does not mean necessarily that this is the optimum place for it in the curriculum. As an example: children can be taught to read at a very early age, but the effort expended and the other problems involved may make it wholly undesir-

able and unprofitable to attempt to teach reading at a very low level.

In a number of curriculum programs, centers of interest have frequently been used as a major basis for determining a sequence. Such centers of interest frequently have become as artificial and as unreal to children as have previous so-called "logical organizations" of the curriculum.

The investigations on grade placements are based on the following factors: (1) present practice, (2) where a unit skill or knowledge is most useful, (3) where it is most interesting, (4) where the pupil is best able to carry it out, and (5) a combination of two or more of these factors. There appear to be two general methods of grade placement—first, by ascertaining the opinion of competent teachers; and, secondly, by means of objective data of difficulty, interest, and other factors. It should be remembered, however, that both procedures are theoretical and tentative. They are subject to correction based upon experience. The best that objective analysis can accomplish is to give a dependable starting point for the grade placement of units of work in the several grades.

If education is considered an evolving process, with the sequence of experiences and their content determined, in part, by the process itself, all aspects of the curriculum cannot be fully seen or outlined in advance. Likewise, curriculum building cannot be segregated from instructional practices and other conditions without seriously affecting the outcomes of the curriculum. Experiences and content should be determined progressively in relation to the ongoing process of teaching and living.

This does not mean that there shall be an unplanned curriculum, for an unplanned curriculum is unsound. It is necessary that there shall be considerable agreement in terms of functional learnings, as to the desirable scope and sequence of the curriculum. The general possibilities in a given learning should be considered and outlined in advance, at least in part. Sufficient flexibility should be permitted so that the learning experiences selected and emphasized are those of most significance to a particular group, and so that both the teacher and the pupils have some part in planning the activities and experiences

in which they are to engage. (See CURRICULUM.) W.H.B.

GRADUATE EDUCATION. After 1900 the M.A. and Ph.D. degrees became generally required for certain types of teaching positions, especially at the college level, whereas in earlier years preparation for research had been the nearly exclusive function of graduate degrees, particularly the Doctor's degree. This development resulted in a large increase in the number of higher institutions that offered graduate degrees. Of late years, more than three thousand Doctors' degrees and in excess of twenty thousand Masters' degrees, distributed over a wide range of fields, have been awarded annually in the United States. To safeguard the character of graduate degrees, as graduate departments have expanded rapidly, a number of national organizations have aided in defining the functions of graduate study and in developing definite standards for the Masters' and Doctors' degrees.

Today the objectives of graduate study may point toward either research or teaching, and more frequently toward a combination of these two functions, with the teaching aim dominant. Recipients of graduate degrees are expected to possess the qualities of research competence, knowledge of the field of specialization, and usually teaching ability, with a much higher level of originality, research competence, and knowledge expected of the doctorate candidate.

The chief requirement for admission to

GRAMMAR, TEACHING OF — GRAPHIC METHODS

graduate work is a Bachelor's degree from a recognized college, with a specified amount of undergraduate preparation in the graduate area selected for specialization. The quantitative standards for the Master of Arts (M.A.) and Master of Science (M.S.) degrees are similar, including a minimum of one year of advanced study above the baccalaureate, or thirty semester hours of graduate work. The Master's thesis is generally required and usually carries credit to the extent of several semester hours, although some schools that offer specialized professional degrees, such as the Master of Education (M. Ed.), have discontinued the thesis.

The Doctor's degree usually represents a minimum of three years of graduate study beyond the Bachelor's degree, with the possibility that in many cases a large part of the third year can be devoted to the dissertation. Some form of dissertation is always required, although the types of Doctors' investigations vary widely, especially for such professional graduate areas as the Doctor of Education (Ed. D.) program.

During recent years a number of problems relating to graduate work have been vigorously discussed in the educational literature: (1) emphasis on theory or principles versus applications to practical problems, (2) the modern foreign-language requirement, (3) over-expansion of graduate departments, (4) availability of suitable thesis and dissertation problems to the extent of some three thousand topics a year for Doctors and twelve thousand or more each year for Masters, and (5) development of criteria for evaluation of graduate instruction.

GRAPHIC METHODS. It is sometimes clearer, more convenient, and more effective

to represent educational data by means of graphs rather than tables. A series of graphs may give the reader all he needs to know, and give it to him quickly. Graphs make it easier to depict trends and to emphasize changes or contrasts. Many graphs have special uses; a percentile graph, for example, makes possible the rapid determination of the percentile value of any score. In careful statistical work it is usually advisable to present both the graph and the table upon which it is based.

There are many forms and variations of graphs, but all of them are adaptations of a few fundamental forms, such as bars, lines, curves, circles, and pictures. The two basic features of almost all graphs and charts are vertical and horizontal distances. When both are used in the same diagram, quantity or amount is indicated by area; but when either the vertical or horizontal is used alone, the amount is indicated by the height or width of the graphic form.

Both the teacher and the school administrator can make use of graphic methods to clarify their approach to the problems which they face. Let us assume that a battery of achievement tests has been administered in a given school during the third month of a school year. Miss A, the teacher of a fifth grade class, finds that her results, in terms of grade equivalents, are as follows:

TABLE I
Achievement Test Results—Grade V

Pupil	Read- ing Comp.	Spell- ing	Arithmetic Funda- mentals	Reason- ing	Eng- lish	Median Achieve- ment
A	4.10	6.1	5.6	5.8	5.8	5.8

GRAPHIC METHODS

Bar Graphs.

The median results for her class may be presented graphically by means of either a

vertical or a horizontal bar graph (Figures 1 and 2). Since the length of the bars are proportional to the amounts represented, it is easy to visualize the quantitative results.

Fig. 1. PRESENTING IN THE FORM OF A VERTICAL BAR GRAPH THE MEDIAN SCORES SHOWN IN TABLE I.

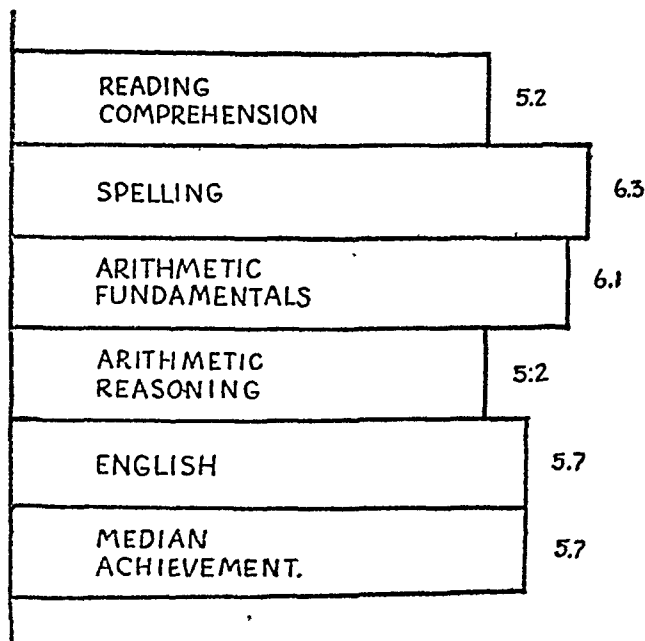

Fig. 2. PRESENTING IN THE FORM OF A HORIZONTAL BAR GRAPH THE MEDIAN SCORES SHOWN IN TABLE I.

GRAPHIC METHODS

The school administrator often finds it necessary to compare the scores made by all the classes on a grade. A *multiple bar graph* (Figure 3) may be used for this purpose. While multiple bar graphs have the advantage of presenting graphically a considerable amount of data, it is ordinarily difficult to comprehend them by quick inspection.

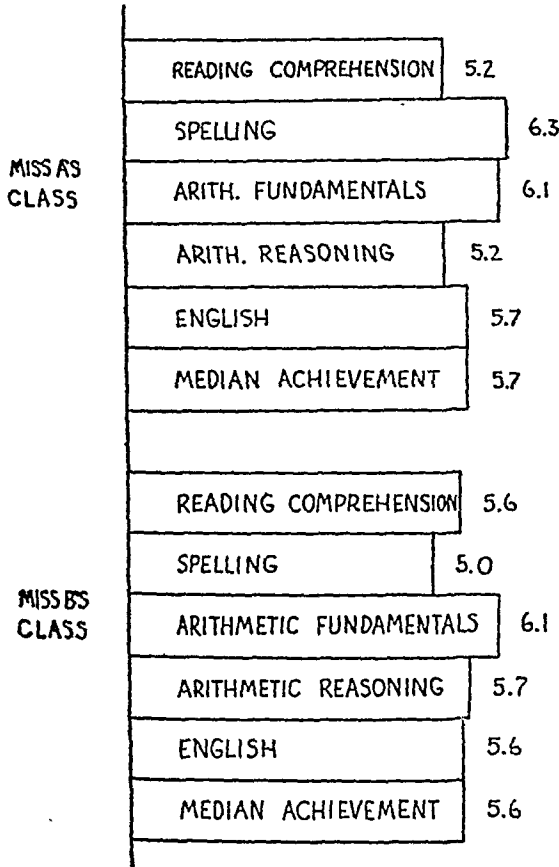

Fig. 3. PRESENTING IN THE FORM OF A MULTIPLE BAR GRAPH A COMPARISON OF MISS A'S CLASS AND MISS B'S CLASS.

Another variation of the bar graph which the administrator finds helpful is the *100 per cent bar graph*. Both vertical and horizontal bars may be divided into parts, each representing a portion of the whole. Thus, Figure 4 illustrates the distribution of reading comprehension scores given in Table I.

Fig. 4. PRESENTING IN THE FORM OF A 100 PERCENT BAR GRAPH THE READING COMPREHENSION SCORES SHOWN IN TABLE I.

An adaptation of the bar graph in which rows or columns of human figures are used to represent numbers of people has been developed in recent years. Similarly, money bags are used to represent expenditures, houses to represent construction of school buildings, etc. Such *pictorial bar charts*, as they are known, can be utilized very effectively by school boards to present statistical material for public consideration.

An additional adaptation of the bar graph makes use of a diagram of a thermometer in order to indicate change over a period of time. Thus, the number of books collected from day to day for the Victory Book Campaign is indicated on the thermometer by raising the height of the "mercury" as the campaign progresses.

Still another variation of the bar graph is the *histogram*, which is generally used to represent a distribution of continuous values. While the histogram does depict continuous values satisfactorily, in a truly statistical sense it should be reserved for the presentation of discrete data. An example of the teacher's use of the histogram is given in Figure 5, which presents the distribution of median achievement scores given in Table I.

Fig. 5. PRESENTING IN THE FORM OF A HISTOGRAM THE MEDIAN ACHIEVEMENT SCORES GIVEN IN TABLE I.

Circle Graphs. The *circle* or *sector graph*, like the 100 per cent bar graph, is used to show the parts which make a whole.

Thus, it may readily be used to show percentages of children enrolled in elementary, junior, or senior high school, the expenditure of the school dollar for salaries, supplies, repairs, etc., and similarly for other factors and quantities. The sectors are often shaded or colored to show the portions more clearly. Numerical values should accompany the various sectors of the circle graph. Since it is not always easy to judge the relative size of sectors, numerical values will aid in making comparisons. An example of a circle graph is given in Figure 6, which presents a breakdown of the median achievement scores given in Table I.

Fig. 6. PRESENTING IN THE FORM OF A CIRCLE GRAPH THE MEDIAN ACHIEVEMENT SCORES GIVEN IN TABLE I.

Line Graphs. When a curved or broken line is used to represent data, vertical distance along the ordinate usually indicates number or amount, while distance from left to right along the abscissa or base line usually represents succeeding time intervals. Values such as income, prices, rainfall, pressure, and an almost unlimited number of other items may be indicated on the vertical scale.

The teacher and the school administrator will find many uses for simple line graphs. Thus, the teacher of a fourth year class may chart the average progress of her children in arithmetic fundamentals for a given month, while the administrator may find it helpful to indicate average attendance in his school during each week of a school year. An ex-

ample of a line graph, illustrating a teacher's progress chart is given in Figure 7.

Fig. 7. AVERAGE PROGRESS IN ARITHMETIC FUNDAMENTALS OF A FOURTH GRADE CLASS.

When a line graph begins and ends at the base line, a surface is defined which is ordinarily called a *frequency polygon*. Like the histogram, the frequency polygon is a graphic representation of a frequency distribution. In both cases, the frequency is indicated on the vertical axis, and the steps or class intervals on the horizontal axis. The points which determine the frequency polygon are placed above the mid-points of the class interval and opposite the appropriate frequency. An example of a frequency polygon, based on the median achievement scores shown in Table I, is given in Figure 8.

Fig. 8. PRESENTING IN THE FORM OF A FREQUENCY POLYGON THE MEDIAN ACHIEVEMENT SCORES SHOWN IN TABLE I.

The shape of the frequency polygon gives an excellent indication of the nature of the distribution. High and low points and irregularities show how the data are distributed, and can be readily interpreted. Frequency polygons can also be used more readily in comparing two classes than either multiple bar graphs or histograms. Because of the oblique lines used, it is easier to compare two distributions plotted on the same base line by means of the frequency polygon—similarities and differences stand out much more clearly. Technically, however, the histogram is more exact than the frequency polygon, in that the area in each successive class interval is directly proportional to the number of cases in that interval.

Another means of representing a frequency distribution is through the use of a *percentile curve*. The curve is constructed by computing several percentile (*q.v.*) points by means of which a graph can be drawn which indicates

the percentile values for the entire distribution fairly accurately. An example of a percentile curve, based upon the arithmetic fundamental scores shown in Table I, is given in Figure 9.

The percentile curve has a typical form which is reproduced fairly well in the above diagram. It should be noted that the smoothed curve shown does not pass through all the percentile points plotted.

The percentile curve may be used by the teacher and the administrator in many ways. Median and quartile scores, as well as measures of variability such as the variation of the middle 90 per cent of the group, may be read directly from the graph. When two or more percentile curves are drawn on the same pair of axes, the overlapping of scores can be readily determined.

Pictograms. A pictogram is a means of setting forth both quantitative and qualitative material in pictorial form. In one type of

Fig. 9. PRESENTING IN THE FORM OF A SMOOTHED PERCENTILE CURVE THE ARITHMETIC FUNDAMENTAL SCORES GIVEN IN TABLE I

pictogram, the quantitative trend in school enrollment is portrayed by varying the sizes of persons who are representative of the data involved. Another form of the pictogram presents the same data by using pictorial representations of the same size throughout, and varying their number. In most instances, it is better to use the latter approach, since, when the magnitude of objects is used to show a trend, a common error of considering only dimensions and not areas often arises. In representing growth in college enrollment over a period of years by students of different sizes, for example, a doubled enrollment should not be shown by a student twice as tall, since the resulting figure will be more than twice as large if area is taken into account.

Qualitative factors may be shown pictorially by comparing equipment and facilities of former years with those of the present. Thus, comparisons may be indicated by using horse-drawn vehicles and motor trucks, stage coaches and streamlined trains, one-room school houses and multi-storied consolidated schools, etc.

Cartoons. Cartoons, as used in educational as well as in other fields, rarely attempt to portray an accurate and statistically correct picture of actual data. In most cases, general quantitative concepts, such as decline and increase, together with actual or implied causes and effects are presented. The use of cartoons, for the most part, is restricted to gaining ground for a point of view.

GRAPHIC RATING SCALE—See RATING SCALE.

GREAT BRITAIN, EDUCATION IN
See ENGLAND AND WALES, EDUCATION IN.

GREECE, EDUCATION IN. Organization of Education. After the fall of the Byzantine Empire in 1453 the Greeks

lived for about four centuries under the rule of the Ottoman Empire; a revolution took place in 1821, and in 1830 Greece was recognized as an independent state.

The country to which the name Greece was given was but a small part of the Greek soil. Many struggles, occurring in different periods, were ended by the Treaty of Lausanne, which determined the boundaries of Greece as they were before World War II.

While the struggle for independence was going on and the military needs were absorbing the thoughts and all the poor financial forces of the insurgents, in the First National Assembly, which took place in 1824, a committee was organized for the purpose of "forming and suggesting a plan of organization of Elementary, Secondary and Higher Education." The Greek representatives, worthy of the history they themselves had gallantly written with their blood and of the long line of their glorious ancestry, did not forget the importance of education—a social activity upon which Modern Greece was to be based.

Elementary education was established as compulsory in 1834, in an epoch during which many of the most important European states had not yet taken such a measure. The small Greek state began its life with 71 elementary schools and 6,721 pupils of both sexes. In 1837 the secondary schools and the University of Athens were established.

Greece in all of her life confronted the educational problem seriously and all the Greek leaders—in spite of the successive wars that absorbed the greatest part of the resources of the country—fixed as one of their aims the development of education.

Elementary Education. *Maternal schools* were organized especially for the northern districts of Greece. Among the 500 maternal schools, 50 had two classes and the remaining had one.

Boys and girls began their training in the *elementary schools* at the age of six years. A minimum of 15 pupils was required to justify the appointment of a teacher. The elementary schools were composed of six grades, compulsory for the pupils who did not intend to continue their education further. The pupils who were to attend secondary schools left the elementary schools after the fourth grade and were admitted to the secondary

schools only after passing a special examination. In the elementary schools in which there were foreign pupils the law provided for a teacher of their language and religion.

Although education was compulsory, there were adults who had not finished the elementary school. For them elementary *night schools* were organized. Five persons were sufficient to justify the forming of a class.

The teachers of maternal schools were trained in nursery training schools having a four-year training period. Students were admitted to these schools after having finished the elementary school and having passed a special examination.

The teachers of the elementary schools were trained in the Pedagogic Academies, which had a four-year training period. Students were admitted to these academies after having finished the *Gymnasium* and having passed a competition. For every Pedagogic Academy two elementary schools, one with one class and one with many classes, were adjoined. Elementary school teachers with a successful career of six years were given an academic training for further studies in special courses of the universities, agricultural courses, and famous educational centers abroad.

Secondary Education. This was furnished in (a) *Gymnasiums*, with training periods of six years; (b) *Lyceums*, with training of two years. These follow the *Gymnasium*. The *Lyceums* are divided into *Classical Lyceums* and *Real Lyceums*. Graduates from the *Lyceums* can be admitted to the competitions for higher education); and (c) *Astika Schools*, which were equivalent to the *Gymnasiums* but had programs that also included special lessons according to the kind of school it was (i. e., agricultural, commercial, technical, or home economics).

The professors of the secondary schools and of the Pedagogic Academies were doctors or graduates of any one of the Greek universities. In addition, the professors of pedagogy studied in foreign pedagogic centers. The professors of physical training were trained in the Academy of Physical Training.

Elementary education was supervised by the Inspectors of Elementary Education. Greece was divided into 90 inspectorates who were under the supervision of the General Inspectors of Elementary Education; the latter

reported to the Board of Elementary Education.

Secondary education was supervised by 20 General Inspectors who in turn were supervised by the Board of Secondary Education. Both elementary and secondary education were under the supervision of the Supreme Board of Education.

Higher Education. In 1835 there was organized in Athens a "Higher School of Medicine, Chemistry, and Surgery," and in 1837 the University of Athens was founded. In 1836 a "Sunday Polytechnic School" was organized. In 1843 it became a daily "school of arts" and in 1882 it became a "Polytechnic Institute." Before World War II the Polytechnic Institute contained the following faculties: Engineers, Architects, Electrical Engineers, Chemical Mechanics, Topographers. To the Polytechnic Institute was annexed a secondary Polytechnic School (for architects, geometers, calligraphers, etc.). Other schools of higher education in Greece are the University of Saloniki (1925), the Superior School of Agriculture (1920), the Superior School of Commercial and Financial Sciences (1920), the Panteios School of Political Sciences (1920), the School of Evelpidon (Army), the School of Dokimon (Navy), the School of Icaron (Air Force), and the School of Telegraphy.

Professional Education. In addition to the Theological Faculties of the universities there were in Greece before World War II the Rizareios Seminary and four Secondary Theological Schools.

In addition to the Superior School of Agriculture there were: a Faculty of Higher Studies of Agriculture in the University of Saloniki; three private Superior Schools of Agriculture; Agricultural Asylums for orphans of both sexes; courses of agriculture which comprised a one to two years' training period (The students in these agriculture courses were teachers who after their training were placed in schools of agricultural districts and taught in the Sunday Schools of Agriculture. They also took care of the school gardens, being assisted and directed by the Ministry of Education and the Ministry of Agriculture. There were gardens in all the schools of elementary and secondary education); Sunday Schools of Agriculture for adults; and Ambulant Schools of Agri-

culture (training of one to three months).

In addition to the Superior School of Commercial and Financial Sciences there were 13 Secondary Commercial Schools (training period 5 years); 6 Private Secondary Commercial Schools; and 6 Secondary Commercial Schools annexed to private schools.

Besides the National Polytechnic Institute there were Secondary Technical Schools requiring three years of training, and Professional Asylums for Orphans (11 for girls, 5 for boys, and 5 private asylums for both sexes).

In addition to the Faculties of Medicine and Surgery of the Universities there were 3 schools for nurses, 2 schools for obstetrics, 1 school for hygiene, and 1 school for specialists of disinfecting.

There was one School of Mercantile Navigation.

Besides the Elementary Night Schools of General Education there were 7 Professional Night Schools and 2 Secondary Night Schools of Mechanics (five years' training period).

Schools of higher education in fine arts included the Superior School of Fine Arts, Secondary School of Fine Arts, Odeon of Athens (organized in 1871), Hellenic Odeon in Athens, National Odeon in Athens (the last two named had branches in many other towns), Musical Lyceum, and School of Dramatics.

Outstanding Educational Movements. During her life as an independent country, Greece adjusted her educational system to the social currents of the time. But even in that effort she kept the "measure".

After World War I, when Greece sought to establish and assure the friendship of her neighbors by official acts, the programs of her schools were adapted to this national movement. Fortunately, in the composition of those programs the existence of an incorrigible neighbor in the Balkan Peninsula and the growing ambitions of Nazism and Fascism were not overlooked, and when the time came for defense the Greek youth was ready morally also.

Table 1 presents comparative figures which show the tremendous growth of education in Greece during the past 110 years.

Table I

School year	1829-1830	1938-1939
Population	753,400	7,108,000
Elementary Schools	71	8,192
Pupils	6,721	825,000
Percentage	0.88%	11.8%
Secondary Schools	39	398
Pupils	2,528	60,980
Percentage	0.33%	1.09%

Relations with the United States. In Greece there were many foreign schools operating under the supervision of the Ministry of Education. Among those which were the most appreciated were the American schools (colleges for boys and girls in Athens and schools of general and of agricultural education in Saloniki). In opposition to the German and Italian Institutes, which were centers of espionage, the American schools operated with the purpose of teaching the language and the ideals of the United States to the youth of Greece and of strengthening the friendly bonds that have always united these two countries. The same is to be said for the American Archeological Institute.

As for the American Societies, which so generously and kindly assisted the Greek refugees of 1922 and came to the aid of Greece in her effort to rehabilitate them, their assistance has been very much appreciated.

No official information about the modification of the Greek educational system by the invaders during World War II is available (1943), except the fact of the introduction of the German and Italian languages in the schools of all grades. E.G.S.

GREEK, TEACHING OF—See CLASSICS, EDUCATION IN.

GROWTH AND MATURATION. One of the most obvious facts of human development is the growth in size with age and maturity. Less obvious are the differential rates of growth for different organs and different parts of the body, and the fact that physical growth, even after birth, means change not only in size but in structure and in function. If the various organs and parts of the body were measured and weighed at birth and compared with the size they would reach at maturity, it would be found that the proportions they had already reached varied considerably. In general, the head, and the parts of the body toward the head, as well as the

parts closer to the spine, have at birth reached a larger proportion of their growth and henceforth grow at slower rates than those more distant from the head and spine. This variation in birth size is in line with the cephalo-caudal and proximo-distal direction of prenatal development. The head of the newborn child is extremely large compared with the rest of the body; it grows slowly and is of almost adult size by the age of six. In later years the head may not grow in size, but the proportions of its features change and the general countenance takes on an appearance easily recognized as immature, mature, or aged. The trunk and the limbs, on the other hand, grow right through childhood and adolescence. The internal organs of the body, as well as the skeletal parts, also differ from each other in the amount and the rate that they will grow. Between infancy and adulthood they change both in gross proportion and in comparative size.

Not only do the growth curves for different parts of the body differ in the length of time over which the curve extends, and in the degree to which the curve is accelerated, but each curve is itself irregular. These irregularities of rate of growth are themselves different for different parts of the body and, to an appreciable extent, for different individuals. Even during the first year of life the rate of growth is not constant. The baby, for instance, increases his birth weight much more during the first four months than during the last four of his first year. Height also increases irregularly. The most rapid growth occurs in the prenatal period and in the first two years. By the end of the first five years most children have doubled their birth length. A prepubertal spurt occurs frequently, with another spurt at adolescence.

Individual differences in the pattern of the growth curve can to some extent be categorized as group differences. Shorter and taller children have been found to differ in the pattern of their height curves. There are sex differences as well. Girls, as a rule, have their growth spurts at earlier ages than boys and also stop growing at a younger age. This means that in early adolescence girls may be actually taller and heavier than boys of the same age, though at all ages boys are the stronger.

Height curves for girls are much more

alike for girls with the same menarcheal age than for girls with different menarcheal ages. Similarities within a family of height and weight and the ratio of weight to height have been observed frequently. What the inherited factors are is not clear but it is agreed that we do not inherit body size itself, but rather factors which influence body size. That size is influenced also by environmental and nutritional factors is also evident from the fact that the present generation is both taller and heavier than the previous generation.

Since persons of the same chronological age differ in the rate at which they are approaching physical maturity, other indices of physical age have been sought. Height and weight have been discarded as being least indicative. The two most common measures used are those of bone ossification and of the maturation of the genitalia and of secondary sex characteristics. Infants have very little mineral deposit in their bones which consist largely of cartilage. Increasing age brings increased mineralization but here, as elsewhere, there are individual differences in rate of development. X-rays, usually taken of the wrist, indicate the degree to which mineralization has taken place. A comparison with age norms will yield the "anatomical age." Sometimes this term is used also to cover or include physiological age, the age which refers to the stage of pubescence. In childhood, dentition is sometimes used as an index of anatomical age. Differences in anatomical age ranging from 4 to 6 years have been found among children of the same chronological age. For any given child, the various measures of anatomical age correspond closely.

Investigations of brain growth have been of interest partly from the viewpoint of the relationship of such growth to the growth of intelligence. The growth of the brain has been studied both with respect to the development of total brain mass and with respect to alterations in structure. The human brain grows to about four times its birth weight. Both brain and spinal cord grow rapidly in the early years, reaching about ninety per cent of their full growth by the time the child is six years old. According to present-day evidence, the increase in mass size of the brain is not accompanied by an increase in the number of brain cells present at birth.

GROWTH AND MATURATION

Brain weight, whether measured absolutely or as a proportion of body weight, has not been found to correlate with intelligence. For a single individual, of course, brain weight and intelligence increase together during the early years.

Increase in mass is not the only form in which brain maturation takes place. In the adult nervous system, the white matter, but not the grey, is composed of fibres each covered with a white fatty sheath known as a myelin or medullary sheath. (See NERVOUS SYSTEM.) This development of myelin sheaths around neurones takes place after birth. The time when myelinization occurs is different for different regions of the brain and the hypothesis has been put forth that the brain regions which are myelinated earlier reach functional maturity earlier. There is disagreement, however, as to whether myelinization is necessary before the neurones can function. Another development of neurones is their terminal branching, which grows richer as the brain matures. While it is not clear just what factors in neural development affect intelligence, it is certain that growth of the nervous system and growth of intelligence are interrelated.

The interrelatedness of the multiple factors which influence growth in its various aspects often makes it difficult to study the influence of a single factor, but experiments can be arranged from which inferences can be drawn as to the contributing value of any one growth factor. It is, for example, evident that exercise as well as nutrition contribute to growth. While the effect of exercise cannot be separated from the effects of other growth factors, it is possible to determine whether a child will acquire a particular motor behavior by a specified age even if he is not practised in it. Studies of infants show that motor behaviors common to the human race, such as sitting up and walking, depend largely upon the maturational level of the child. Direct training may hurry the ability somewhat, but not to any great extent. On the other hand, motor abilities which are more individual, without which the human race could get along (e.g., skating) often show very decided practice effects. A certain stage of physical maturation is needed before practice can take effect, but once that maturational level is reached practice and progress go along to-

gether. Practice begun at a later maturational level may bring a higher rate of progress. A problem that is receiving a good deal of attention is whether practice that is begun at a later age will eventually lead to the same degree of skill as practice begun earlier and continued. It is probable that with some skills the differences will be slight, with others, rather considerable. The difference will also depend upon the gap between the ages when practice was begun. Many of the maturation studies have shown that when young children are given practice in some skill for a few weeks or months and are tested some time after the training has been discontinued, they show no greater ability in the skill than the control children who received no practice whatsoever. Another important finding is that growth with its changes in body proportions often changes the manner in which certain motor tasks are performed. Change in the manner of performance may result in a lower degree of skill.

While the matching of learning tasks to the maturational level of the child is important for the efficiency of the training, it is equally important for the health of the child. The child's heart is much smaller in proportion to the aorta than is the case in adulthood. If exhaustion is not to result, there must be plenty of rest and sleep. Even in adolescence, care must be taken that there is no overexertion. While vigorous exercise is necessary for the growing body, it should not be too prolonged. Strain also results from the child's attempt because of school pressure to acquire a skill beyond his maturational ability. Even the demand that the child maintain a certain posture may be too great. Good adult posture is impossible for children who have bodies of such different proportions from the adult. It must always be remembered that the child is not a small-sized man. The child lacks certain characteristics which he will have when he grows to maturity, and some of the adult characteristics he has in only elementary form. Moreover, growth in motor and mental coordination depends more upon increased complexity of the organism than it depends upon increased size.

Since the various growth processes of the organism are partly independent of each other and partly interrelated, it is difficult to place a child at a level of maturation. There

is no criterion for grouping which will bring about homogeneous groups. Since physical and mental development have only a low positive correlation, it has sometimes been suggested that children be placed in one group for tasks largely of a mental nature and in another group for motor and manual tasks. This will reduce, but not eliminate, the heterogeneity of each group with respect to the classifying criterion. Many motor abilities are themselves correlated only to a small degree. In the playground, a child who is with his own size group may find himself in competition with children older than he is who have had more time to acquire the skills needed for their play. Moreover, he may be behind them in social development, as important a factor in the choice of friends as physical and intellectual development. The child who is small for his mental or chronological age will have similar difficulties. If the teacher is to help the child find a group with whom he can fit in, the child's development and that of the other children in the several areas rather than in only one will have to be considered.

Norms of physical and motor development are often misused. Since norms merely record the average for a group of children who have been measured, they carry with them no implication that deviations above or below the norm are good or bad. Neither does the degree to which large deviations are common tell us whether such deviations should be a cause for anxiety. The treatment and guidance of each child should depend not only on the degree and type of deviation but on his general well-being. Another important factor to consider is whether growth in the various functions is so disparate that maladjustment will necessarily result. An eleven-year-old girl who is sexually mature, emotionally immature and mentally-retarded for her age will meet many problems which she will need help in solving. A very tall five-year-old boy may have no more ability to defend himself than other five-year-olds, and yet the six- and seven-year olds treat him as an equal with whom it is legitimate to have a fight. In the area of maturation, the dictum to take account of the "whole" child is not only a meaningful one but an essential one.

GUESSING. Guessing is possible on any kind of test, but it is not a serious problem except on examinations where the student has considerable probability of hitting upon the correct answer. For example, the student has a 50-50 chance of guessing the correct response on true-false tests, but his chances are negligible on essay examinations and very small on other recall tests. Guessing is not important unless it affects the reliability or the validity of the test. (See OBJECTIVE TESTS AND EXAMINATIONS.)

In general, four proposals have been made to offset the factor of guessing in recognition tests. One obvious possibility for reducing the frequency of guessing is to instruct students not to guess at doubtful items. How effective such instructions would be in reducing the extent of guessing depends on many variable factors, such as the students' willingness to take a chance and the importance they attach to the examination. Another proposal is to use tests where there are several options, such as matching tests or multiple-choice tests with at least four suggested answers. While the use of matching tests and multiple-choice questions does not reduce the prevalence of guessing it does reduce the likelihood of a student's making the correct response simply by guessing.

A third proposal is to use the so-called correction or scoring formula. The general form of this formula is:

$$S=R-\frac{W}{n-1}$$

In this formula, S is the score, R is the number of right responses, W is the number of wrong responses (this does not include omitted responses), and n is the number of possible responses to each item. For example, in alternative-response tests, such as the true-false, n is 2. Hence, the formula becomes $S=R-W$. Similarly, in 3-response tests it becomes $S=R-\frac{1}{2}W$; in 4-response tests, $S=R-\frac{1}{3}W$; and so on. In actual practice no correction for guessing is usually made, if there are five or more possible responses.

In theory the formula attempts to give the student the score he deserves rather than the one he may happen to make. On any particular test he may receive either more or less than he deserves, but he is likely to get what he is entitled to in the long run. The experimental results have shown usually that the use of the formula affects the reliability only slightly, but tends to improve the validity. It should not be assumed, however, that the use of a formula for correction is a complete solution to the problem of eliminating the students' guesswork in an objective examination. It is obvious that the laws of chance do not apply to the limited sampling that is found when a pupil guesses the answers to five or six true-false questions on a test containing one hundred items. Moreover, the formula does not provide for errors due to misreading or misinterpretation, since the assumption is made that all errors are the result of chance.

A fourth suggestion is to make the tests somewhat longer than usual. If the added items are of the same quality as the others, both the reliability and the validity of the test will be increased. The student who receives a high score by consistently guessing the correct responses on a long list of items is more likely to be a superior student than is the one who gets a high score because he is lucky at guessing the correct answers on a much shorter test.

GUIDANCE. To many persons the aim of guidance, simply stated, is to help every individual develop the best that is in him as an individual and as a member of the groups to which he belongs. From this central aim stem all the principles and procedures included in the terms *guidance* and *student personnel work*. *Guidance* is the term more commonly employed in elementary school and high school; *student personnel work* and *personnel work* are the terms more frequently applied to similar work in college and industry.

The concept of guidance has changed in the course of years. In any age one may find quotations that represent the broad view of guidance expressed in the first paragraph of this article. Even after more than thirty years of widespread interest in guidance, there is still no unanimity of opinion and practice. More confusing still is the common discrepancy between theory and practice.

Certain trends, however, are perceptible:

1. The trend toward increasing the teacher's responsibility for guidance.
2. The trend toward the guidance of the individual as a whole, in all his many-sided aspects, life guidance rather than merely educational guidance or vocational guidance.
3. The trend toward developmental guidance which makes remedial guidance less necessary. In other words, the modern guidance worker is concerned with the best development of every individual rather than with the treatment of "problem cases" only.
4. The trend in vocational guidance toward emphasizing individual flexibility and adaptability based on self-knowledge rather than toward the choosing of a specific vocation.
5. The trend toward encouraging the individual to assume as much responsibility as possible for his own guidance—for making his own way in a complex world. In other words, the counselor serves as a consultant working with, rather than working on, the individual being "guided."
6. The trend toward recognizing the social aim for guidance as well as the aim of helping the individual attain personal success and happiness.
7. The trend toward viewing guidance in its educational, social, and economic setting; in other words, recognizing conditions within the school and society, such as policies of promotion, attendance, discipline, curriculum

GUIDANCE

offerings, and employment opportunities, which make effective guidance possible—or impossible.

✓These trends imply certain principles of guidance. Of central importance is the principle of respect for every individual. This naturally involves a recognition of individual differences and leads to an acceptance of the person as he is—his abilities, interests, needs, assets, and faults.

✓An essential supplement of such acceptance is the principle of growth. The personnel worker not only accepts an individual as he is, but focuses attention on what he may become. By keeping in mind the individual's potentialities, the personnel worker will help him to grow according to his own best pattern.

Part of every individual's potentialities is a certain capacity for self-direction. This the personnel worker will recognize and he will be concerned with helping the individual help himself—to see relationships among people and events in his experience, to think through his own problems, to gain insight, and to make plans. One way in which the personnel worker can appraise the effectiveness of his work is by noting the extent to which individuals and groups with whom he is working become increasingly capable of carrying on desirable activities by themselves.

These three guidance principles—acceptance, progression, and self-direction—should permeate guidance procedures. The study of individuals (including the keeping and use of records), guidance in the on-going activities of classes and clubs, counseling, group discussions, and committee work—these are the means by which the objectives of guidance may be realized.

In accomplishing this task every member of the school staff plays a part. The administrator creates conditions that make effective guidance possible. He selects well-qualified teachers and specialists in guidance, gives them work suited to their abilities, and through in-service education helps them to grow in their guidance responsibilities. He is also largely responsible for school policies of attendance, promotion, discipline, and for curricular offerings which meet every pupil's needs. The teacher guides while he educates. Knowing each pupil as a person, he can give him, at the moment of his greatest readiness,

appropriate experiences, information, and counsel. As homeroom teacher, class adviser, teacher-counselor, or core curriculum teacher, he occupies a position midway between classroom teacher and specialist. The specialist in guidance—dean of girls, dean of boys, vocational counselor, psychological counselor, and visiting teacher—by virtue of his position, training, and experience may be expected to have more expert knowledge and skill in this field, to be able to deal with more complex problems, and to have the background and time for cooperation with guidance agencies in the community. The specialist will use his time most efficiently by working with and through teachers. He can greatly extend his influence by supplying teachers with up-to-date and accurate vocational information, by working with them on individual cases, by demonstrating techniques of group work, by discussing with them concrete guidance problems which they are facing, and by periodically studying the cumulative record of every pupil with his teachers.

Under such leadership, the guidance influence will gradually affect administrative and teaching procedures. Pupil needs, when recognized, will lead to modifications of the curriculum, of the school schedule, of school policies, and even to modifications of the physical plant and the teaching personnel. The guidance point of view will lead to a fuller understanding of every pupil and consequently to individualization of instruction.

The guidance process includes work both with groups and with individuals. It is obviously uneconomical to give to individuals one by one certain information that can as effectively be imparted to groups. Moreover, guidance in social living cannot be given except in groups. The ways of democracy are not acquired in a vacuum nor is a social individual developed in solitary confinement. The good adjustment of some individuals, however, cannot be effected merely by providing group experiences for them. Only on the basis of an understanding of these individuals can they be guided into experiences they need and be helped to profit from their participation in group activities. A smaller number of students are not able to profit by any group experience without clinical treatment. These require expert psychotherapy by means of which they may gradually gain insight into

GUIDANCE

their experiences and relationships and learn how to modify their behavior so as to meet normal life situations.

There is no ideal guidance program that will be suitable to every school. The form of program will vary with the size of the school, the qualifications of the teacher, the leadership of the principal, the financial resources, the philosophy of education, and many other factors. Two criteria, however, may be applied to any type of program: (1) Does every pupil have as his counselor some congenial person who knows him as a whole, and (2) is the quality of the group work and the counseling good so far as it goes?

In the individual elementary schools all over the country, there are practically no guidance specialists. Guidance of children and parents is the responsibility of the teachers and principal. Each teacher serves as the counselor of her class, becoming acquainted with each of her pupils and using the resources of the school and the community to meet their individual needs. In the vast majority of small high schools the same lack of specialists in guidance prevails. In all these schools principals and teachers need assistance. This assistance may be given by a supervisor from the state department of guidance, a county psychologist or guidance worker, a trained counselor employed by a small group of schools conveniently located, or a committee of teachers each of whom has obtained some special training in guidance. In larger high schools having an effec-

tively functioning homeroom (*q.v.*) organization, the homeroom teacher serves as counselor for her group; in a core curriculum setup, the core teacher is the counselor. Another form of organization is one in which the best qualified teachers are selected as counselors of perhaps a hundred students, and are freed for two periods a day for individual work with their counselees or for home visits. A more centralized form of guidance program is that in which a director of guidance, chief counselor, or dean of girls and dean of boys assumes responsibility for the program as a whole. In every instance the success of the program depends upon a leader with vision and skill, teachers well qualified by personality who are willing to learn and willing to grow, and sound, practical in-service education. (See VOCATIONAL GUIDANCE.) R.M.S.

H

HABIT. The word *habit* is used in both common speech and educational literature to designate a wide variety of learned activities from the socially undesirable to the highly ethical; from bodily skills, such as walking, to mental activities, such as the habit of critical thinking; and from specific abilities to generalized attitudes. The meaning of habit includes the idea of facility in the performance of an act combined with a persisting inclination toward a repetition of the act. The emphasis may in one case be on the skill of performance and in another upon the motivation to act, but neither aspect is excluded in typical habits.

The educator is concerned both with the formation of useful habits from infancy onward and with the elimination of undesirable habits which have already been formed. Since motivation and skill are both functions of the environment as well as of the learner, habits are established most readily when the environmental conditions support their acquisition and maintenance. Social customs in a particular community are thus strong factors in determining the habits formed by an individual growing up in that group. The continual provision of opportunities for action and of appropriate facilities for action is necessary for the adequate establishment of a habit.

One common error in educational practice has been an overemphasis on repetition as the essential factor in habit formation. Such emphasis neglects the factor of interest in the activity and overlooks the consequent real danger that forced repetition of an act distasteful to the individual concerned may drive him into opposed activity. In any case, even if the performance is learned under force, the activity usually ceases when the force is removed. Motivation toward an act is of primary importance, although practice of the act is essential also in habit formation.

Another criticism of emphasis upon repetition as the main factor in habit formation

arises from the high degree of adaptive change involved in many kinds of habitual action. A skill, such as handwriting, is maintained with certain characteristics that we call habitual, but it also involves a great many changes at each performance because of varying equipment and conditions. Likewise, the habits of courtesy and of critical thinking involve intelligent adjustment to circumstances in order that persistent movement in a general direction is maintained. Not only does habit formation in the majority of cases involve varied practice rather than exact repetition, practice that is varied until the performance is improved to a point of satisfaction, but the habit when learned and acquired as a disposition shows certain novel features each time it is displayed. The availability of routine action helps a person to perform readily and efficiently, but complete bondage to the previous manner of performance is dangerous when changing circumstances require modified action.

The fear that repetition will inevitably cause a habit to be formed has led to teaching techniques which restrict the student to performances done under minute direction and with as close imitation of the model as possible. Teachers have been afraid to let children make mistakes, under the assumption that those mistakes would immediately constitute habits. They have failed to distinguish between the effect of "mistakes" that the learner himself regards as mistakes and the effect of "mistakes" that the learner regards with satisfaction as adequate and proper performances. Even when a habit has been formed that it is later desired to change, the "breaking" of it is a much less arduous task in some instances than in others. In fact, it is sometimes not an arduous task at all. In the same way that different amounts of repetition and different conditions are needed for the establishment of different habits, so the elimination of undesirable habits cannot be reduced to a simple, invariable rule. In a

few cases habits have been eliminated by intentionally repeating the action with an awareness by the victim of its undesirability. In other cases a gradual substitution of new motives and new patterns of action has replaced those that were less desirable. In still other instances, it has been possible to eliminate suddenly forms of action that had become habitual.

Likewise, the degree of intelligent awareness by the individual concerning the habits he is establishing or eliminating may vary. A child or older person may have an habitual fear or affection established without any awareness of the process, while on the other hand a person may intelligently choose to practice a certain act or attitude until it becomes a habit that facilitates his effectiveness. In the majority of cases, likes and dislikes, prejudices for and against, the manner of walking and talking, "mannerisms," and the like are habits acquired with little, if any, deliberate intent, while most skills require deliberate practice.

In the field of skills, where the final habit is never attained at once, the term "hierarchy of habits" is used to indicate the sequence of levels of attainment. For example, a person may begin to use a typewriter with one finger "hunting and picking." He may later move up a step to the use of three or four fingers on each hand, but to reach full efficiency he needs training in the "touch" system in which all ten digits come into coordinated action. From one step to another in such a hierarchy there may occur some interference, but on the other hand the previous practice even with one finger may contribute to the higher skill and more effective habit. While teachers need to develop in children habits appropriate to their stages of development, the prospect of replacing at a later time early habits with those that are more mature and complex must be kept in view as a guide in the process. The habits which should be developed are those that will serve immediate needs and at the same time will contribute to the development of habits higher in the learning hierarchy.

Narrow conceptions of the neural organization underlying the formation of particular habits have led to treating habits as though they were independent and separate parts of the individual's action pattern. Mod-

ern views of the integrative action of the nervous system, however, support emphasis upon the interrelation of all aspects of behavior to each other and the treatment of any habit as an integral aspect of the individual's total behavior. In considering how to establish, modify, or eliminate any habit, the teacher needs to keep in view the effect of any practice not only upon the particular habit but also upon the whole personality of the learner and the direction of his conduct toward socially desirable ends.

HANDEDNESS. The treatment of hand preference in the child is a complex and confused problem partly because of the wide range of explanations offered and partly because the relative influence of the various factors involved differs in different individuals. The explanations offered for *dextrality* (preference for the right hand or side) include (1) functional domination by one half of the brain, presumably due to hereditary predisposition; (2) position *in utero*, the hand which is most free to move being preferred in early childhood and thereafter; (3) the social, environmental pressures of a right-handed world, which are exerted incidentally, without adult awareness, or intentionally by parents and teachers. Preference for the right or left hand (preference for the left hand being

known as *sinistrality*) develops gradually during the first year, but according to actual handedness tests of children and adults, 100% right-handedness is not often found in individuals at any age level. Tests of handedness include measurement of bones, muscles, and strength of grip, as well as observation of a wide variety of activities in which the individual uses one or the other hand, eye, or foot; e.g., reaching, throwing, writing, picking up small objects, threading a needle, hopping, sighting through a small hole in a paper, or folding hands or arms. Not all of these differentiate handedness equally well. Psychologists are not agreed as to the degree of relationship existing between eyedness and handedness nor concerning the significance of this correlation.

Interest in the handedness of children arises from three assumptions: (1) the left-handed person is at a disadvantage in a right-handed world; (2) bad consequences follow when a left-handed person changes over to the use of the right hand; and (3) ambitextrous (or ambieyed) persons suffer certain confusions and incoordinations. Observations and experimental studies are cited both to support and to negate these assumptions. There seems as much contradictory evidence as there are contradictory theories on the subject.

The problem of handedness has arisen with regard to three school subjects in particular—writing, reading, and speech. In the first, the struggle of the teacher to make the child use his right hand may certainly lead to stress and emotional difficulty with a hatred of school caused by the continual badgering received during the very first school year. Moreover, writing is difficult enough for any beginner, but writing with the hand that is less coordinated and skillful may seem like an impossible task. It would appear that if the child has come to school with a definite preference for keeping the pencil in his left hand, the teacher should help him arrange his writing materials and the position of his hand in such a way as to facilitate good writing with the left hand rather than to spend the time in forcing him to change hands.

In reading, reversals (*q.v.*) are sometimes attributed to a confusion in cerebral dominance, in which the brain fails to work consistently from either the right or the left hemisphere, and also to the difficulty that

left-eyed children may have in making eye movements to the right. Remedial measures proposed by experts in the teaching of reading rarely suggest any policy with regard to handedness but do advise exercises, such as moving the finger along the line, to help the child in reading from left to right.

Stuttering, which has been found to occur proportionately somewhat more often among left-handed children than among right, has been related to handedness in two ways; to lack of dominance of either of the brain hemispheres and to emotional upset caused by forcing the child to change from the right hand to the left. Most speech pathologists agree on the significance of the latter relationship. If this were the only relationship between stuttering and handedness, remedial measures would consist of helping the child to develop right-handedness in his first two years of life and, in cases where change must be made thereafter, of doing it with as much patience and understanding as possible. A number of speech psychologists, however, seem to hold strongly to the involvement of cortical dominance in stuttering. They believe that stuttering is a direct, rather than only an incidental, result of hand-change. The advisability of a shift from the right to the left hand together with special exercises for improving left-handed skills is seriously put forward by Travis for those stutterers whose childhood history or whose scores on handedness tests show a large degree of left-handedness or ambidexterity. The proposal goes as far as suggesting that a plaster cast be put on the right hand to immobilize it in the case of young children and of the mentally retarded who can not be trusted to keep on using the left hand by themselves. Such drastic proposals highlight the confusion and partisanship that can arise with regard to the solution of a problem where factors and relationships are involved and indistinct, and where there exists a vast array of individual differences ranging from children who have been spanked into hand-changing but show no visible ill-results to children who show difficulties as soon as hand-changing is begun.

HANDICAPPED CHILDREN. The handicapped, for the purposes of education, may be divided into four large classifications: (1) the physically handicapped; (2) the mentally handicapped; (3) the socially handicapped; (4) persons with combinations of physical, mental, or social handicaps.

The physically handicapped may be divided into three groups: (1) those whose handicap involves one or more special senses, including the blind, the partially-sighted, the deaf, the hard of hearing, and the deaf and blind; (2) those whose handicap results in motor disability or limitation, including orthopedic cases (infantile paralysis, spastic conditions, osteomyelitis, bone tuberculosis, and congenital deformities, cardiacs, those suffering from respiratory diseases in certain stages, and malnutrition cases; and (3) those with various types of defective speech of whatever origin.

The mentally handicapped include: (1) all persons who in native intellectual capacity fall in the lower ranges of human intelligence—for example, low average, morons, feeble-minded, imbeciles, and idiots; (2) persons who have suffered accident or disease resulting in impairment of mental functions; and (3) persons suffering from emotional instability, psychopathic states, and insanity. Among the mentally handicapped are types educable in regular classes, in special classes, in homes, or in special institutions. At present, the limits of educability of such persons are more or less determined by the native endowment of the individual and the function of education of the mentally handicapped is considered largely a matter of choice and preparation for lower level occupations which involve only simple skill or elementary repetitive mental processes. It is believed, however, that much may be done for the mentally handicapped through provision of opportunities for the enrichment of their lives.

The socially handicapped may be differentiated from the physically or mentally handicapped, though physical and mental

handicaps may be contributory or coexistent, by the fact that their chief limitation in meeting the problems of life appear in behavior maladjustments, for example, in delinquency, destitution, dependency, or crime. The purpose of education should be prevention and rehabilitation. The various types of socially handicapped, even in the restricted sense in which the expression is used, are too many for enumeration in this connection, but they range from those who may be educated in regular or special classes to those who must be segregated in special institutions, in which there are facilities for psychiatric treatment.

In the larger sense the socially handicapped embrace all persons who, through accident, disease, or maladjustment on their own part, or the exigencies of society, fail to achieve and maintain a fairly normal economic and social status. From this point of view, as from the more restricted point of view, the purpose of education is both preventive and therapeutic. (See BLIND, EDUCATION OF THE; DEAF, EDUCATION OF THE; EXCEPTIONAL CHILDREN; JUVENILE DELINQUENCY; MENTAL DEFICIENCY; ORTHOPEDIC DEFECTIVES, EDUCATION OF THE; and UNDERPRIVILEGED CHILDREN.) M.E.F.

HANDWRITING, TEACHING OF. Handwriting is now viewed not as an art but as a tool for expressing thought easily, speedily, and legibly enough to meet present social needs. The American cursive type evolved from the labored writing of colonial days, the ornate Spencerian era of the nineteenth century, and the vertical script stage of the early twentieth century. Manuscript, or print script writing, has shared the field with the cursive type since 1921. Following the Roman model, the letter form of this type is based on the use of circles and straight lines.

Developing well-coordinated arm, forearm, and finger movement, writing posture habits.

and attention to hygienic requirements is the concern of the methodology of penmanship. The teaching of penmanship is essentially the development of skills involving the principles of association and habit formation. Among the components of method in all grades are proper physical conditions, incentives, understanding and imitation of models, correctly spaced practice, and elimination of error. Proper physical conditions include not only the accepted "front position" of the body and the working positions of the forearm, hands, and fingers, but also proper eye distance from the paper, lighting conditions, relative positions of seat and desk, etc. Research indicates that, for children, effective incentives include comparison with standards or with their own or other pupils' attainments, personal approval or disapproval, awards, and the recognition of good penmanship as a means to a desired end. Necessary components in the teaching of correct form and movement are models, blackboard writing, analysis, rhythm, comparison with standards, and self criticism. From the evidence available, incidental teaching of handwriting is less effective than meaningful practice and attention to discovered errors. Practice exercises are of three types: those facilitating control, those needed in acquiring correct individual and grouped letter forms, and those needed in remedial work. To be effective they should be short, distributed, and concerned with meaningful content based on children's experiences. By varying requirements with children's abilities and rendering guidance in remedying errors, essential individualization is achieved. Children who are strongly left-handed should probably not be forced to change. Evidence on the nervous effects of changing in milder cases of left-handedness is inconclusive.

An emerging issue relates to the comparative values of cursive and manuscript writing. The elements of method seem to be the same for both. Experimental findings seem to indicate that, when taught to young children, manuscript is the easier to learn, is more legibly and rapidly written, and leads to more rapid learning of reading and spelling. In the upper grades cursive writing is more rapid than manuscript and also more legible when done more slowly. Children can learn both, and the shift from manuscript to cursive

penmanship is usually arranged at the end of the second grade.

Quality and speed are the chief elements tested in penmanship. In a timed speed test children write familiar or memorized material. Quality, or legibility, is measured by comparison with specimens on standardized scales of two types. One type—the Thorndike or Ayres scales and the Conard Manuscript Writing Standards—measures general ability. The analytical type—the Freeman scale for example—is used for diagnosis. Use of scales is known to yield more reliable appraisals than unstandardized judgments.

HARD OF HEARING CHILD — See DEAF, EDUCATION OF; HANDICAPPED CHILDREN; SPEECH CORRECTION.

HARMONIOUS DEVELOPMENT. The concept of harmonious development, whether outspoken or not, permeates all education, for naturally man considers harmony as a desirable goal. The question is not whether harmonious development is one of the objectives of education—it is—but how to achieve it. The answer to this question will depend on an educator's set of values from the realization of which, according to his opinion, harmony can be gained. From the classical Greek thought, harmony in man comes from his intellectual identification with the great laws and ideas in the universe, in other words with the *Logos* or *Kosmos*; for the Christian, harmony comes from faith and devotion to God's eternal will; in Comenius the concept of *Nature*, already known to ancient philosophers, again emerges. Harmony, according to Comenius, comes first of all from faith in God and his commandments, but it also requires an education which respects the "natural" laws of physical, moral, and mental growth.

In a more naturalistic, sometimes also in a pantheistic, form the concept of Nature plays a central role in Rousseau's thought. According to him harmony is possible only after man's return to "Nature." The profoundest ideas about harmonious education have been expressed by Pestalozzi, who combines consideration of the physical, psychological, and environmental conditions of harmonious growth with a deep insight into its spiritual conditions.

According to his Romantic philosophy of the essential unity between Spirit and Nature, Froebel conceived of education as the process which enables man to realize in himself the inner harmony of the universe. Like many other philosopher-poets (Plato, Goethe, Schiller) he recognized the importance of art and play as a means of achieving that physical-emotional-mental equilibrium which enables man to perceive form and unity in the diversity of being. In spite of their intuitive approach Pestalozzi and Froebel have anticipated many results of modern research into the "subconscious" levels of the mind, which, as we know nowadays, are of essential importance for a person's harmony. The same is true of Herbart, whose emphasis on many-sidedness and equilibrium of interests betrays his concern with harmonious development. Since the times of Rousseau and Pestalozzi increasing stress has also been laid on the notion that an individual can achieve harmony only if he is permitted to realize the productive trends and potentialities inherent in his own specific personality, as it develops in relation to its specific environment and purposes (individual differences). In modern education, psychology and psychoanalysis have tried to explain the conditions of harmony through experimental and analytical research, not seldom forgetting what older educators knew, namely that harmony in man has physical as well as "meta"—or "trans"—physical conditions.

Though the great thinkers of earlier times always saw individual harmony as interrelated with social harmony, modern educators have deemed it necessary to warn of the danger of one-sided individualism and a concept of harmony based on it. They say, correctly, that any socially defensible concept of harmony must have a social as well as an individual purpose. Hence the aim of educa-

tion must be to develop each individual's potentialities not only for his own advantage but also through, and for the purpose of, productive interaction with his fellow men.

The concept of harmony carries with it the same dangers as the concept of happiness to which it is related in many respects; one easily forgets that harmony, as well as happiness, is not simply a state of mind but an achievement. One who wants to understand and appreciate the peace in harmony and happiness must also understand the importance of conflict, grief, and effort in human development. (See AIMS OF EDUCATION.)

HARRIS, WILLIAM T. (1835-1908).

Dr. Harris was primarily a logician and metaphysician, and one of the foremost exponents of Hegelianism in English. His later responsibilities as Superintendent of Schools at St. Louis in the 1870's and as United States Commissioner of Education from 1889 to 1906, to which post he was appointed by President Harrison, brought the educational philosopher into the executive chair where theory could be winnowed and tested.

His work, both before and after administrative burdens came to him, concerned the kindergarten in American education, the elementary school curriculum, and the training of teachers, with related ramifications. In the fields in which he wrote and worked he constantly held certain aims in mind. These aims were to psychologize education; to prove that the school has sociological functions and values; to place education upon an enduring foundation.

The Kindergarten. During the 1850's private German-speaking kindergartens had been set up in various parts of the United States by German immigrants. Some private English-speaking kindergartens had also been opened, notably that by Elizabeth Peabody in Boston in 1860. But the incorporation of the kindergarten into the free public school system in America was an achievement of Dr. Harris, effected during his superintendency of the schools of St. Louis. There, working with Susan Blow, a literal Froebelian, Harris built the kindergarten as the first preprimary

rung on the American educational ladder (1873). (See FROEBEL; KINDERGARTEN.)

Elementary School. Dr. Harris was an influential advocate of the place of elementary science in the school curriculum. In this respect, he may be grouped with Spencer (*q.v.*), Horace Mann (*q.v.*), and others as an advocate of enrichment of the curriculum in the direction of greater attention to science. A somewhat formalized version of Pestalozzi's object-lessons (see OBJECT TEACHING) had reached the United States by way of England, and had flowed into the stream of elementary school practice by way of the Oswego Movement (*q.v.*) and other sources. Against this object-lesson teaching, Harris urged the enrichment of elementary school experience by the introduction of elementary science. The course of study for the St. Louis schools (1871) embodied his views as to what such elementary school science should be.

Beginning as early as the third year of the elementary school, the growing child was to be initiated into the highly systematized organization of knowledge covering both inorganic and organic nature. This introduction he believed must be very gradual; the attendant scientific nomenclature must not be allowed to inhibit clear understanding; well selected "types" must be used as a base for wide generalization; the method must stress observation of concrete materials. Yet, with all these protective method qualifications, Dr. Harris' thinking well typifies the logician at work on the elementary school curriculum. From the adult logical retrospective viewpoint, there is a potent tendency to impose on the mind of a growing child the severe, systematized, classified, rubrics which it has taken some centuries of cumulative thinking to evolve.

Since Dr. Harris wrote and worked, a quite different conception of the optimum introduction to the study of natural phenomena has gained wide acceptance. This is nature study, and it has come to replace science in the Huxley sense, which was the sense in which Harris understood it. Nature study is the simple, observational study of the common things of nature, from the standpoint of their relation to daily life, independent of the organization of science. The issue is

between the logical and the psychological approach to the open book of nature.

Dr. Harris was much concerned with the place of "industrial education" (practical arts) (*qq.v.*). He urged its place in the kindergarten, to develop "activities of muscle and brain," so that deftness and delicacy of industrial power in all later life might be secured. He believed that such arts should be omitted from the elementary grades, to be returned to with a pointedly vocational aim above the elementary level.

The Teacher. Dr. Harris has bequeathed a provocative conception of the function of the normal school, still relatively young in America in his day. He believed that it should not concern itself with the rudiments of the subjects to be taught by the intending teacher, however professionalized these subjects might be. He believed, on the contrary, that it should lead the prospective teacher to re-examine the elementary branches in relation to *all* human learning. The lower branches of knowledge should be taken up in relation to the higher: arithmetic should be reconsidered in the new light of algebra and geometry; geography should be illuminated by the normal-school study of geology. In sum, Harris believed that he who would teach must himself be educated; that he who would teach a paragraph must know the whole related chapter. P.R.V.C.

HATCH ACT. The Hatch (Pernicious Political Activities) Act of Aug. 2, 1939 as amended July 19, 1940 (53 Stat. 1147, 54 Stat. 767. 18 U.S.C. 61) was designed by Congress to prevent the use of federal moneys in partisan political activities and campaigns, by placing restrictions upon the political activities of persons whose employment is in an activity for which the Federal Government contributes funds.

Despite an early ruling of the Attorney General of the United States apparently to

the contrary (Circular No. 3301 of the Attorney General, Washington, Oct. 26, 1939, p. 3, Sec. 3), the Act was interpreted to apply to certain groups of teachers. The United States Civil Service Commission, to which administration of the Act is committed by Congress, ruled that it applied to: (1) faculty members of land-grant colleges, regardless of how their specific salaries are financed; (2) instructors in vocational education under the Smith-Hughes Act; (3) teachers of vocational agriculture; (4) employees of a university experiment station or extension service of a College of Agriculture.

However, by Public Act 754, 77th Congress, 2nd Session (October 24, 1942), Congress amended the Hatch Act so as not to apply those provisions prohibiting political activities to "any officer or employee of any educational or research institution, establishment, agency, or system" operated publicly or by "any recognized religious, philanthropic or cultural organization." The amendment will probably meet most objections toward the original Act frequently voiced by leading teachers' associations. H.N.R.

HAZING. Hazing—the subjecting of new members of colleges, fraternities, or other groups to ridicule or other punishment as part of their initiation—is clearly on the wane in this country. Its avowed purpose is to make the newcomer realize his relatively minor importance and to prove his willingness to self-sacrifice, as well as to celebrate his admission to the group or institution. Sometimes confined to an hour or two, hazing occasionally extends over an entire year. Until the last decade hazing of men was frequently so severe that many colleges sought to control or abolish it (e.g., *School & Society* 29:201-4 F9, 1929). Recently sev-

eral conditions have helped to lessen greatly its severity and prevalence: the desire and need to make colleges attractive to the best high school graduates, large cross-sectioned house or dormitory groupings, the greater number and attractiveness of other extracurricular activities, the decreasing isolation of the college, the larger number of day students, and the increasing social significance of college studies and consequent increased seriousness of purpose and maturity among students. M.G.F.

HEALTH. Health is technically defined as "that condition of the body in which all the functions are performed normally." Evidences of health in children are found in normal growth, freedom from remediable defects or impairments, good nutritional condition, a minimum of days lost because of illness or accident, and sound mental attitudes. The relationship between pupils' health and their success in school has not been unequivocally established.

Recently some educators have broadened the medical definition of health, by considering it as a resultant of "completely wholesome, well-balanced, interesting living." Others think of health in terms of its end result—being able to "live most and serve best." A really adequate idea of health would include all three views of health—as a physiological condition, as a resultant of good living, and as an "ideal of vigor and efficiency."

According to this concept of health, standards must be individual. There is only one general standard—the best health possible for each individual. In order to attain this standard the individual needs an environment conducive to health, guidance in that environment, knowledge and skills required in making wise choices relating to healthful living, and self-determined goals and purposes which direct him in healthful ways. Two important factors in the total health program are the health of the teacher and the school health services.

In order to be "fit to teach," teachers should attain the best health possible. It is encouraging that the death rate for teachers is lower than that for the general population, that nervous diseases do not seem to be more common among teachers than among other occupational groups, and that city teachers

probably do not lose much more than five days annually because of illness. Teachers need to be on their guard especially against respiratory diseases and emotional instability. As one means of promoting the teacher's health the annual medical examination is generally recommended. Thus incipient health problems can be detected and the necessary treatment secured. In at least one large city all candidates for teaching positions or for permanent tenure as teachers must submit to a test for a possible tuberculosis condition. (See **TEACHERS' HEALTH**.)

The school health services which provide for the care of accidents and sudden sickness in school, periodic health examination, and a follow-up program to insure the needed medical and dental care require trained personnel—physician, dentist, and nurse. The school physician is concerned with the promotion as well as the protection of children's health. His influence is extended a hundred-fold as he works with and through teachers, the nurse, guidance workers, and physicians in the community, instead of devoting practically all his time to the examination and treatment of individual children. The nurse likewise can help the teacher gain proficiency in some of the simpler tests of vision and hearing, in the detection of communicable diseases, and in gaining the cooperation of parents in obtaining these necessary corrections or treatment. Especially during emergency periods when there is a serious dearth of medical, dental, and nursing service, it is more important than ever that these health specialists carry on an active instructional program involving the cooperation of teachers, parents, and pupils. Thus the special school health workers, instead of functioning merely as the state laws require, in the control of epidemics and in the medical examination and inspection of children, perform an important educational rôle in the improvement of children's health, broadly defined.

The present programs of school health service have reached a higher state of development than any other single public health service. They are most successful when integrated with the rest of the school program and with other community activities. The school's responsibility to provide a healthful environment for its occupants has been recognized from the first. Standards have

been established for ample floor space, adequate playground room; a suitable water supply, proper toilet facilities, proper illumination, and seating which prevents fatigue and encourages good posture. The example of clean, attractive, and well kept schools helps pupils learn the value of cleanliness and the proper care of facilities and equipment. The inculcation of these habits it is hoped will carry over to the care of the home.

The periodic examinations made by the physician should be educational, thorough enough to be serviceable, and effectively followed up. Although the annual medical examination is desirable, health educators in school systems with limited medical facilities have recommended the following ways of having the school physician make the best use of his time: (1) by examining all pupils less frequently than once a year, (2) by providing "annual examinations only for those students who cannot afford the services of a family physician," and (3) by "selecting for reexamination and follow-up only those students with definite health problems." Thus the school doctor will be enabled to do more effective medical and educational work with those students whom he examines.

If the parents of elementary school children are present at the examination and are as eager as the child to know what to do to improve the child's health, "an unparalleled educational opportunity" is offered. Unless the significance of each item of the health examination is understood and appreciated by the parent and child, even obvious defects frequently remain uncorrected.

With high school students, the school doctor would not usually invite the parents to the examination. He would take it for granted that the student was ready to assume primary responsibility for his own health. At the end of the day the doctor might hold a conference with the physical education teachers, counselors, and administrative officer in touch with the student in order to make any adjustment of program or instruction that was indicated and thus make it administratively easier for the student to get started on the road to correction of defects and improvement of his health.

Thus the gap between the examination and the necessary follow-up is quickly bridged. Records are another means of making the

medical examination function. These should be of two types: (1) the medical record on which the technical findings of the physician and his opinions and recommendations are recorded; and (2) the pupil's health card on which the teacher records her daily observation of the child's appearance and health behavior, absence due to illness, results of tests of vision and hearing, height and weight, dentist's report, doctor's statement made to the mother and his recommendation to the teacher as to what she can do for the child's health. This card would also provide space for the nurse's follow-up and the teacher's summary of the pupil's health. In high school, students may take responsibility for keeping their own health record and should discuss their progress with their adviser once or twice a semester. Thus the health of children and young people, so crucial to the welfare of society, will be promoted by the most efficient use of health specialists, by the growth of teachers in the health program, by an increased sense of responsibility on the part of pupils and parents, and by more effective coordination of the contribution of all who have a share in the health program. (See COMMUNICABLE DISEASES OF CHILDHOOD.)

HERBART, JOHANN FRIEDRICH

(1776-1841) was a native of Oldenburg, in northwestern Germany. He came from a well-to-do family; his father was a learned public official, and his mother was a woman of exceptional intelligence who carefully supervised the early rearing and education of her gifted son. Between the ages of twelve and eighteen, Herbart attended the Gymnasium of his home city, from which he was graduated with the highest honors. He entered the University of Jena to prepare for the practice of law. At the University he studied under Fichte and was deeply influenced by the new humanism which prevailed there and by his associations with a brilliant group containing such creative geniuses as Herder, Goethe, and Schiller. Finding that he had little taste for the study of law, he left the University to become the private tutor to the three sons of the Governor of Interlaken, in Switzerland. While in Switzerland, he visited Pestalozzi's school at Burgdorf and wrote sympathetically of what he observed there. From 1802 to 1808 he lectured on education and philosophy at the University of Göttingen, where he published his famous *Science of Education*. For the next twenty-six years, he held the chair of philosophy at the University of Königsberg, formerly occupied by the great Immanuel Kant. Here he founded a pedagogical seminar, a practice school for teacher-training and experimentation in methods of teaching, and published in 1835 his monumental work, *The Outlines of Educational Doctrine*, a clear and practical exposition of his educational ideas.

In Germany, the influence of Herbart was carried into the second half of the nineteenth century by Ziller, at the University of Leipzig, who founded the Association for the Scientific Study of Education, and extended the Herbartian methods into the elementary schools. Rein, a pupil of Ziller's became head of the pedagogical seminar and practice school at the University of Jena, and made it the great center of European Herbartianism. The Herbartian movement reached the United States late in the century when a group from the Illinois State Normal School, including Charles DeGarmo and Frank and Charles McMurry, went to Jena to study, and brought back the new science of education. In 1892, the National Herbartian Society was organized, the name being changed later to the National Society for the Study of Edu-

cation (*q.v.*). Most of the normal schools, particularly in the Middle West, were soon won over to the Herbartian principles and methods and, through the teachers they sent to every section of the country greatly influenced the practices of our schools.

Herbartian Aims. According to Herbart, the ultimate goal of education is the development of moral character. He regards steady, dependable moral personality as the highest aim of humanity, and consequently of education. Herbart believed that the ultimate goal of moral personality could be attained only through the development of a group of desirable, abiding, many-sided interests. The aim of education is to analyze the interests of man to discover which are best for individual and social living, and then by means of instruction to enable the individual to develop and apply these interests in the various situations of life. By producing a well-balanced many-sidedness of worthy interests, education endeavors to develop in the youth the will to be good and the desire to make sound moral choices. Thus a high degree of personal character and social morality will result.

Before Herbart, educators aimed at teaching morality through the use of preaching, precept, and the memorizing of moral maxims. Centuries of experience have demonstrated the futility of this method. Herbart believed that moral conduct must be based upon the development of the will, and that will-attitudes depend upon the accumulation of experiences, so organized as to express themselves freely and constantly in intelligent moral decisions. "We will what we know; we cannot will what we do not know." This is Herbart's justification of his aim of "many-sided interests." Herbart believed that the main purpose of education is the growth and development of ideas in the mind of the child, brought about in conformity with psychological laws.

Herbart himself aimed at the development of the youth rather than of the child, and, differing in this respect from most of the other developmentalists, concerned himself more with secondary than with elementary education. Most of his followers, however, applied his philosophy and methods to the field of primary education.

Herbartian Curriculum. Herbart outlined the materials of instruction in terms of

his doctrine of interests, classifying all subject matter in terms of typical human interests. Man's interests, he said, were derived from two sources: (1) his contacts with real things of his environment, or sense impressions; and (2) his contacts with other human beings, or social intercourse. He believed, therefore, that the content of education should consist of two types of studies: (1) studies about things, such as sciences, mathematics, and fine arts; and (2) studies about people, such as languages and history.

The Pestalozzians had already emphasized and developed the first group of subjects. Of the second group, however, Pestalozzi had concerned himself only with oral language. It remained for Herbart and his followers to introduce and foster history and literature as subjects of preëminent importance in the curriculum. Herbart himself was concerned primarily with the application of his theory to the study of languages, literature, and history in the secondary schools. Ziller, however, seeing the value of Herbartian-taught history and literature as a means for developing the morals of the child, made story-material from history and literature the basis of the content of the elementary curriculum. The Herbartians have favored history particularly as a study of primary importance in developing good human relationships and good citizenship. As a result of the influence of the American Herbartians, history and literature have become important subjects in our elementary course of study. History, previously limited to the upper grades with the sole aim of developing national patriotism through the study of American history, is now taught in all grades, drawn from all sources, and aimed at social and moral results as well as civic. Literature, originally used as models for expression and taught by means of a few selected classics, is now taught for its moral and æsthetic values with material drawn from the whole range of children's literature.

Herbartian Method. Interest is at the basis, too, of the Herbartian method. Skillful teaching is the ability to stimulate interest without resorting to force on the one hand or sugar-coating on the other. The details of his methodology are in fact statements of ways in which interest, the *sine qua non* of "educative instruction," can best be aroused. Herbart took Pestalozzi's principle that

learning must proceed from the known to the unknown and elaborated it into the doctrine that new knowledge is always assimilated in terms of what the learner already knows. The pupil must be in the proper frame of mind to attend to the new experience, and must have a stock of recalled related ideas which will enable him to interpret and respond to the new situation. Since Herbart called these related revived experiences "apperceptive masses," this principle is known as the "doctrine of apperception."

Herbart insisted that only large, connected units of subject matter are able to arouse and keep alive the deep interest of the child's mind. This he called the "doctrine of concentration." Concentration occurs when the attention is completely absorbed in one line of thought, when the mind is wholly immersed in one interest to the exclusion of all other interests. Effective reactions of will and conduct come only when the whole of consciousness has been focused on one single unit of thought. Herbart supplemented this doctrine of concentration with the "doctrine of correlation," which makes one subject central in the focus of attention, but sees to it that this subject receives support from all other related subjects. These doctrines were implemented in the five steps of instruction popularized by the followers of Herbart as the "five formal steps of the recitation":

(1) *Preparation.* This is the process of reviving in consciousness the related ideas from past experience, which will arouse a vital interest in the new material and prepare the pupil for its rapid understanding and assimilation.

(2) *Presentation.* This process involves the presenting of the new material, in concrete form unless there is already ample sensory experience, and in such a way that it is closely articulated with "the apperceptive mass," or past experience.

(3) *Association.* This is the process of assimilating the new experiences, by using analysis and comparison to point out points of likeness and points of difference between the new and the old, thus enabling the new idea to take its true place in the mind's understanding.

(4) *Generalization.* This is the process of forming general rules, laws, and principles from the analyzed sensory experiences, thus developing general concepts in addition to

sensations and perceptions in the mind's structure.

(5) *Application.* This process consists of putting the generalized idea to work, sometimes merely to test it, sometimes to deepen the impression by expression, and sometimes to put the idea to use in a purely utilitarian sense.

Dewey has challenged the "formal steps" of the Herbartians on the ground that thinking occurs only when there is a real problem. Another weakness of the Herbartian method was their attempt to use the "formal steps" in the planning of all types of teaching, in the lesson for skill and in the appreciation lesson, as well as in the thought lesson. We owe a debt to Herbart, however, for developing a more complete educational psychology and a better organization and technique of classroom instruction. (See *INDUCTIVE-DEDUCTIVE METHOD.*) E.H.W.

HETEROGENEITY — See **HOMOGENEITY**; **VARIABILITY**.

HEURISTIC METHOD. This word comes from the Greek, *heurisko*, to discover or to find out, a meaning that still holds. The student is given the basic responsibility of solving the problems that confront him. The term is essentially synonymous with problem method or development method. In this country the expression is used very little. For a good example see CHARLES DE GARMO, *Principles of Secondary Education* (Macmillan Co., New York, 1908), Vol. II, p. 178. W.R.

HIGH SCHOOL—See **SECONDARY EDUCATION**.

HIGHER EDUCATION. The term "higher education" usually refers to formal education provided for graduates of high schools or preparatory schools—i.e., to education given by colleges, graduate schools, and professional schools. In particular, it

refers to that given by institutions accredited by the regional accrediting associations and by the chief professional associations which require at least high school graduation for entrance. Thus, higher education may be given, for instance, by colleges or schools of liberal arts, commerce, home economics, music, education, physical education, agriculture, engineering, law, medicine, theology, religious education, or graduate study.

In 1900 there were about 168,000 students enrolled in such schools, in 1920 about 517,000, and in the regular school year of 1938-39 about 1,350,000. The enrollment in 1942 included about 200,000 in separate junior colleges, 130,000 in teachers' colleges, 16,000 in the collegiate divisions of normal schools, and 100,000 in graduate and professional schools. These totals do not include all of the 430,000 summer session students or the 296,000 other students of collegiate rank in adult courses.

Having such a broad meaning, the term higher education is not entirely justifiable. It refers to instruction in both manual skills and highly theoretical subjects, as well as to much instruction of lower quality than that of many secondary schools and of some unaccredited schools for adult education. By uniting the first two years of college and the last two of high school, the University of Chicago has further complicated the task of defining the meaning of higher education.

In fact, it is doubtful that the term can ever be accurately defined, for stages of education merge into and overlap one another. On the other hand, it may be defined some day in terms of education for mature people which is beyond reach of adolescents (i.e., education concerning the more complex problems which fully responsible people alone can understand), or in terms of education which assumes a background of secondary school education, or in terms of both. JOHNS' COLLEGE PROGRAM; STATE COLLEGES and UNIVERSITIES; and such articles as AGRICULTURAL EDUCATION; ENGINEERING EDUCATION; JOURNALISM EDUCATION; MEDICAL EDUCATION.)

M.G.F.

HISTOGRAM—See GRAPHIC METHODS.

HISTORY, TEACHING OF—See SOCIAL STUDIES, TEACHING OF.

HISTORY OF EDUCATION. The study of the history of education did not receive much serious attention until toward the close of the 18th century. Two factors influenced the awakening of interest in the educational thought and practice of the past. The first was a growing tendency to evaluate human life and progress by comparison with past civilizations. The second was a desire to formulate certain standards derived from the past in order to counteract the proposals of revolutionary radicals.

The first real history of education, the *Traité des Choix et de la Méthode de Études*, was written by a Frenchman, Claude Fleury, and was translated into English by S. Keble in 1695; the first part is devoted to a history of studies down to the Renaissance, and the second part to a theory of the curriculum. In the century that followed there appeared many histories of individual schools, but no general history of education. In 1829, Christian Schwartz wrote in German a comprehensive educational history of most of the nations of antiquity. He believed that the history of education is a branch of the history of civilization, and that an account of the past gives insight into the present. This practical value of the study of the history of education was recognized in a number of histories written in Germany after 1830. The work of Karl von Raumer in 1847, more than any other, has exercised an influence on histories of education written in English. He devotes the greater part of his work to biographies of educational leaders as expressions of the educational ideals of their periods. The first histories of education in English followed the work of Von Raumer as a model, the majority having been content to give accounts of educational leaders and their theories. Henry Barnard, in issues of the *American Journal of Education*, published contributions on the history of education, most of them being translations of parts of Von Raumer's work. A number of these articles from the *American Journal* were published in 1863 in a volume entitled *German Teachers and Educators*, this being probably the first history of education in English. A

similar volume on English educators was published in 1876. A work which was used well into the early years of the 20th century was Quick's *Educational Reformers*, published in 1868 and expanded in 1890. Other widely used texts appearing during the last decades of the 19th century were Browning's *Educational Theories*, Painter's *History of Education*, Williams' *History of Modern Education*, Munroe's *The Educational Ideal*, and Seeley's *History of Education*.

The history of education was not taught in France until late in the 19th century, and it too was influenced by Von Raumer. Gabriel Compayré, professor of philosophy at the University of Toulon, began the movement in France with a series of educational lectures, which resulted in his *History of Educational Theories in France*. His *History of Pedagogy* was translated into English by W. H. Payne, as were a few volumes of his series, *Pioneers of Education*. As a result of the Von Raumer influence, many of the courses in the history of education were taught in the United States under the title "Educational Classics", and were devoted to a study of the great educators and their writings.

The publication of Thomas Davidson's *History of Education* in 1900 marks a change in the method of writing educational history. This is the first English text which is not mainly biographical; rather it is an attempt to trace educational development as a phase of the development of culture and civilization. The most popular and influential textbook in the United States was Paul Monroe's *Textbook in the History of Education*, published in 1906. It attempted to show the relation between educational development and other aspects of the history of civilization, and to deal with educational tendencies instead of with men. It was the first real history of educational philosophy, but it did not neglect to make evident the relations of theory to practice. Its organization set the pattern for most of the books that followed. Monroe's work, like Ellwood P. Cubberley's *History of Education* (1920), made constant reference to source material; in fact both Monroe and Cubberley prepared collections of such source material to accompany their textbooks. Frank P. Graves, who wrote a three-volume *History of Education* in the years between 1910-13, also wrote in 1912 his *Great Educators of*

Three Centuries. More recent textbooks in the general field include Duggan's *Student's Textbook in the History of Education* (1927), Messenger's *An Interpretative History of Education* (1931), Eby and Arrowood's *The Development of Modern Education* (1934) and *The History of Education, Ancient and Medieval* (1940), Wilds' *The Foundations of Modern Education* (1936), and Knight's *Twenty Centuries of Education* (1940). In addition, many works have been written on the history of special fields of education; for example, S. C. Parker's *History of Modern Elementary Education* (1914) and more recently I. L. Kandel's *History of Secondary Education* (1930).

The history of education was one of the first subjects used in the professional training of teachers. For decades, along with psychology, philosophy of education, and methods of teaching, it made up the professional curriculum in teacher training. With the rapid development of the scientific movement in education after 1910, however, history and philosophy of education were gradually crowded out of the curriculum to make room for the newer professional courses. In our own country, history of education courses were limited largely to the history of education in the United States, making use of such texts as Cubberley's *Public Education in the United States* and Knight's *Education in the United States*. In the last few years, however, a new interest has developed in the history of education, particularly as an integration with the philosophy of education. The subject is rapidly returning to the curriculum, not as a mere survey of the development of educational institutions and practices, but as a study of the development of the educational theories and concepts that underlie changing practices, as a background for the interpretation of current issues and problems. There is a tendency to subordinate such matters as the development of school legislation and school administration, and to stress the development of the educational philosophies that have influenced educational practices through the centuries, evaluating these in terms of current needs and problems.

Educational leaders of today seem to agree that a thorough understanding of the historical and philosophical backgrounds of education is essential for any intelligent inter-

pretation of educational issues and for any effective participation in the solution of educational problems. A study of the educational ideas and practices of the past leads to an evaluation of those that have survived, and so prompts us to reject those that have outlived their usefulness. It helps us to become thinking educational workers, intelligently progressive in the selection of the aims, subject matter, and processes of modern education. It gives us materials to use in our own creative educational thinking, and develops within us certain valuable attitudes such as humility and patience. The study of what great teachers have attempted and conceived as possible should stimulate us to complete their work and carry out their ideas under the easier conditions and more favorable environment of today. It is an excellent introduction to nearly all professional educational studies. It contributes to the development of that professional spirit without which great achievements are impossible. It is of value not only as a professional study for teachers, but as a part of the general education of all. A study of the educational aspirations of mankind is one of the best approaches to a knowledge of the history of civilization, and an excellent approach to the study of the principles of social, economic, and political reform.

HOME AND SCHOOL COOPERATION. The desirability of developing mutual confidence and active collaboration between home and school has been increasingly recognized in recent years. Emphasis upon considering the "whole child" as an integrated person has inspired efforts to insure a community of aims and methods among all who deal with children.

In many instances, though by no means invariably, the movement toward better home and school cooperation has been initiated and promoted by educators rather than by parents. This has been due partly to specific attitudes

of submission to or rebellion against school authority, engendered in parents early in their own school experiences, and partly to discrepancies, both real and apparent, in information and general educational background between laymen and professionals. In recent years, attempts have been made to place home-school relationships on a more reciprocal basis, first, by acknowledging the fact that parents as well as educators have many contributions to make to the common aims of both groups, even though these contributions may be very different, and, second, by pointing out that the work of the school is hampered and the child confused if home and school are using widely different methods.

In general, efforts to secure home and school cooperation, whether undertaken by schools or by parents, in groups or as individuals, fall under two main headings: (1) sharing information and insight regarding children and (2) participation in common activities. School administrators and teachers frequently wish to secure a great deal of information from parents regarding their children's physical, emotional, and social development. Home visiting by teachers, partly for the purpose of obtaining information, is encouraged in certain schools and occasionally even required. In other schools, visiting teachers or specialists in parent education serve as liaison officers between home and schools; at times the use of *grade advisers*, teachers who act as consultants for both the children of a certain grade and their parents, is found. In some schools an elaborate system of records embodying all this material is maintained.

The information which parents wish from the schools may be factual regarding a child's progress or it may be an interpretation of the general educational goals and methods characteristic of the school. The differences, sometimes profound, which exist between educational policy as it is today and as it was when many parents were themselves in school have created a great need for interpretation of this kind. Bulletins, individual conferences, grade meetings, children's assemblies, opportunities (such as "Open School Week") to visit and observe the school in action, all serve to increase a parent's understanding of his child and of his school.

Areas in which information shared by

schools and parents has been successfully utilized for the benefit of children include health and safety measures, the wise planning of a child's day as a whole (including the time spent in doing "homework"), and the recognition and development of special aptitudes.

Participation in common activities occurs when parents and teachers are aware of its advantages and when school equipment, facilities, and personnel are put at the disposal of parents and other groups within the community, as is frequently done in rural areas, and increasingly in cities as well. Participation by parents in school projects rather than community projects, however, is the chief manifestation of activity shared by home and school. The contributions of comparatively untrained parents to the work of the school may include clerical assistance in the office, service as hostesses for visitors, assistance in the library, dining-room, or playground, assistance on class excursions, preparation of materials for the teachers' use, and carrying on charitable activities for underprivileged children in the school or neighborhood. Parents with more specialized training of some sort may teach art or dramatics, or serve as psychologists, social workers, architects, or landscape gardeners.

Participation in common activities has been found to be a valuable means of breaking down barriers which sometimes exist between teachers and parents because of differences in economic position, social status, or educational viewpoint. Thus far, however, participation has been most frequent and intensive in schools where the community of interest between teachers and parents is already great. Such instances afford a good opportunity to expand social, health, and recreational opportunities in the community for adults as well as children. A few private schools which are parent-organized or even parent-owned have served as leaders in achieving a high degree of mutual action by home and school on school policies. At the other end of the scale are schools which maintain contacts with parents only when serious disciplinary problems arise.

In a great many schools, the chief agency for carrying out a program of home and school cooperation is a *parent association* of some kind. The term "parent association"

may refer to any association connected with a school in which parents are included as members, or it may refer to an association of parents only, as distinguished from a *parent-teacher association*, which includes teachers also. The greater freedom from domination by the school which may exist in organizations of parents only is thought by some leaders to be an advantage. Many of the parent-teacher associations in this country are affiliated with the National Congress of Parents and Teachers; the largest federation of parents' associations in any one city is the United Parents' Associations of New York City.

Local organizations vary greatly with respect to their membership, their activities, and the degree to which they have the support of their communities. Much of the initiative in home and school activities has been taken by mothers; yet the tendency for fathers to take an active interest in school affairs has been rapidly increasing. In some cases associations are oppressed by stereotyped or too diffuse programs, cumbrous organizational details, or political domination; many, however, have made genuine contributions to home and school cooperation. In addition to their activities along the lines already discussed, parent associations frequently are active in protecting the financial interest of their schools. They have in some instances succeeded in exerting pressure on their communities for more adequate equipment and facilities of various kinds, and in arousing a more highly developed sense of the community's responsibility to its children. HOME ECONOMICS, TEACHING OF.

Home economics is concerned with the development of satisfactory personal and family living. The areas it includes—Family and

HOME ECONOMICS, TEACHING OF

its Relationships, Family Economics, Food and Nutrition, Housing, and Textiles and Clothing—are indicated by the divisions of the American Home Economics Association, the professional organization of home economists. The particular phases to be undertaken by a given group are determined by the level of maturity and the needs and interests of its members.

Few subjects in the curriculum have appeared under so many names as has this one. Beginning in the 1870's as cooking and sewing, assuming more dignity as domestic science and domestic art (or grouped under the more inclusive term of domestic economy), household arts, or household science, the subject has finally become known generally as home economics. Other titles, such as home arts, homemaking, or family-life education, are sometimes used to indicate a particular approach, but even in these cases the content material is that of home economics.

Home economics is a field rather than a subject; it draws from the natural and social sciences and from the arts the principles which it applies to problems of food, clothing, housing, and home management. As early as 1902, leaders in the field recognized its functional character in the following definition: "Home economics in its most comprehensive sense is the study of laws, conditions, principles, and ideals which are concerned on the one hand with man's immediate physical environment and on the other with his nature as a social being, and is the study especially of the relation between these two factors. In forming a complete definition, however, it may be possible to consider home economics as a philosophical subject, a study of relations, while the subjects on which it depends, economics, sociology, chemistry, hygiene and others, are empirical in their nature and concerned with events and phenomena."

When first introduced into the schools, home economics was too often considered a special subject. With growing recognition of the family as the basic unit of society and of its influence on the development of personality, training for home living is considered an increasingly essential element in general education. This change is reflected in the course offerings in schools. In the elementary

grades, boys and girls together are introduced to homemaking activities and learn to accept responsibility for their share in home life. In many high schools an introductory course dealing with a variety of phases of homemaking develops an ability to meet personal and family life situations. In some cities the home economics teacher is responsible for units dealing with family living, which are included in the core curriculum or are incorporated into a course required of all students, both boys and girls. College courses dealing with problems of marriage and family life have been developed either in the home economics department or through the co-operation of several other departments.

In addition to its contribution to general education, home economics provides training for such specialized tasks as selection, buying, preparation and serving of food; selection, buying, care, and construction of clothing; furnishing, equipment, and care of the home; management and use of personal and family resources of money, time, and energy; protection of health and care of the sick; development and care of children; and social relationships within the home. Invention and research necessitate constant changes in content and method of home economics, while social, political and economic conditions bring shifts in emphasis. A significant example of this is the increasing attention given to problems of consumption, as goods and services produced outside the home replace those formerly secured by the direct efforts of members of the family. Another is the adjustment called for during a major depression or a war in order that the best possible contribution to family and community welfare may be effected.

Beginning with the Smith-Hughes Act in 1917 and continuing through the George-Deen Act in 1936, laws were enacted which enable the federal government to assist the states with the promotion of home economics as the branch of vocational education training for the vocation of homemaking. This aid has made it possible to introduce and maintain work in home economics in smaller communities and has helped to raise the standard of teaching. A valuable feature of classes in vocational homemaking is the inclusion of home experience or home practice carried on by each student under the direc-

tion of the teacher. (See also CONSUMER EDUCATION.) F.L.S.

HOME ROOM. The home room, a modern development of the "report room" or "official class," has become in recent years an important element of the modern secondary school and, to some extent, of the larger elementary school.

The purpose of the home room plan is to play a part in the school's plan for complete guidance—mental, physical, social, spiritual, and vocational. The home room does not accept responsibility for all of these forms of guidance (*q.v.*), but it supplements and applies much that is learned elsewhere, both inside and outside the school. The home room is not the only setting for guidance, but it is a most important one, especially where guidance is decentralized from a one-office to a many-teacher job.

The home room is based on the assumption that the teacher or "sponsor" learns to know his group (25 to 35 students) intimately, and hence, is able to recognize, evaluate, and develop individual interests and capacities. The trend in the direction of the "permanent" membership plan—in which the teacher has the same students throughout their entire school life—obviously makes this personal relationship all the more profitable. In the home room the student himself becomes the "subject" that is studied, and the teacher becomes a guiding personality.

Because of the newness of the home room idea there is still considerable variation in procedures. Usually at least one full period a week is devoted to home room activities. Shorter periods, used for administrative purposes, are really not home room periods at all, merely "report room" periods. All peri-

ods of the day are utilized for the home room, but apparently the most suitable are, in this order, the first and second periods in the morning and the first after lunch.

In assigning students to home rooms many bases are used, such as intelligence or other quotients, curriculum, teacher or student selection, etc. The trend is toward assignment only on the basis of class, for then each room represents a cross section of a particular school-age level.

The home room implies a democratic setting, and practically all home rooms are organized with the usual student officers and committees. Often the school's student council is composed of representatives elected by the various home rooms.

The formal programs of the home room may be classified into three groups, namely, guidance, seasonal, and "free choice," although these are not mutually exclusive. Guidance programs usually represent more or less formal material and provide a definitely organized and continuous "course" throughout the student's school life. This material comes from books and manuals, often developed by the school staff. There is no great agreement concerning the types of guidance most appropriate for particular school grades. Orientation is emphasized in the first term, but occupations, courtesy, thrift, safety, recreations, citizenship, etc., are scheduled in all years.

Seasonal programs are those that are appropriate at particular times during the year—Thanksgiving, Fire Prevention Week, etc. Most of the material for these programs is usually developed and presented by the students themselves.

Free choice programs, which represent open dates, are generally originated, developed, and presented by the group itself.

Many home room programs are really miniature assembly programs and it is a common practice to incorporate them either as a whole or in part in the general school assembly. The home room program offers an excellent opportunity for student comment, discussion, criticism, evaluation, and personal application.

Other home room activities which are commonly scheduled are: home room responsibilities, each room is assigned for a definite period such tasks as assisting in the library, supervising bicycle parking, etc.; home room

HOME WORK

initiatives—each room originates and develops a particular task; competitions—both within the room or between rooms; inter-room visitation; and individual interviewing and counseling.

In elementary schools which are organized along the lines of the activity program (*q.v.*), these functions of the home room may become part of the regular day's work of the class, especially in those periods referred to as "Opening Exercises," "Morning Conference," etc.

Nearly all schools make serious attempts at evaluating the home room by means of critics' reports, informal discussion, formal rating blanks, participation improvement charts, and other devices.

The most common dangers and weaknesses of the home room are: (1) underemphasis or faulty emphasis—a failure to understand and appreciate the potentialities of the setting; (2) incompetent, unsympathetic, and untrained sponsors—not all teachers are competent to sponsor home rooms, although the general policy is to assign all teachers to this work; (3) formalization—making the home room a formal class in guidance; (4) informalization—allowing a looseness that results in nonvital and unorganized programs and activities; (5) blind and slavish copying of programs and activities; and (6) a failure to evaluate. HOME WORK. As generally interpreted by pupils, home work is limited to the written assignment to be handed in the next day or at the next class meeting. It may consist, for instance, of a number of problems to be solved or a theme of so many words to be written. Of course, home work properly applies to any preparation not completed during the class period. As a rule, home work

increases in amount with each advance in grade.

Home work is looked upon with disfavor by many educators, and some schools have longer class periods so that work ordinarily assigned for home study can be done in school under proper conditions and expert supervision. The objections to home work are based on many grounds: conditions at home are often not conducive to good work; students look upon it as a chore and see no objection to merely copying the work done by their classmates or to persuading an older brother or a parent to do the assignment; home work deprives the child of time that should be available for other purposes; and home work is inefficient, for the time consumed is often disproportionate to the value gained. If the home work assignment consistently requires the student to use processes and materials new to him and for which he has not been prepared, it often results in misconceptions and the making of so many errors that much time is spent at the next session of the class merely in correcting the errors made at home, errors that could have been prevented by sufficient preparation in class.

Where home work is used effectively, it is assigned when needed and not as part of a daily or weekly ritual. The amount of home work is controlled so that it does not make excessive demands on the student's time. If the type of home work assigned varies with the child's needs and the nature of class activities, the ritual of a daily written assignment falls into disuse. In such a class, a home work assignment may consist of reading a short story so that the class time may be used for discussing the story. Another may lead the student to listen to a radio forum to be broadcast that evening, and a third may have the student editing a story or a poem he has written. A good home work assignment grows out of motivated and directed activity and enables the students to carry that activity forward at the next class meeting. Properly used, the home work assignment is of considerable value in teaching students how to study. To meet these ends, a good home work assignment will make certain that students know *what* they are expected to do, *how* they should proceed, and *why* they should do the assignment. (See ASSIGNMENT.)

F.A.B.

HOMEMAKING EDUCATION — See HOME ECONOMICS, TEACHING OF; VOCATIONAL EDUCATION.

HOMOGENEITY. Homogeneity refers to the extent to which the members of a group are alike with respect to a single trait or a number of traits. Thus, when pupils are arranged in classes according to some plan of homogeneous grouping (See CLASSIFICATION OF STUDENTS), the pupils in a given class are so selected as to be as similar as possible in such a trait as mental level, school achievement, or interest in painting. How great a degree of homogeneity there must be before the group can be considered as homogeneous varies with the purpose for which the group has been selected. In educational administration, a class may be regarded as homogeneous when the range of ability is as small as is possible under the circumstances. When three sixth-grade classes are to be organized in a school, the principal will believe that he satisfies the principle of homogeneous grouping so far as mental level is concerned if he has the third of the pupils with the highest mental ages in one class, and the third of the pupils with the lowest mental ages in another class. Within any of these supposedly homogeneous classes there will still be a considerable variation in mental ages. In educational research, however, the standards set for homogeneity are much stricter than in ordinary school practice.

Homogeneity demands uniformity or close similarity on the part of members of a group with respect to a specified characteristic or trait. For example, fifth-grade pupils are homogeneous with respect to grade placement in school and children twelve or more but not yet thirteen years of age may well be considered homogeneous with respect to age.

Homogeneity must be specific, in the sense that it applies to only one characteristic or trait at a time or to several, but not many, characteristics or traits taken in combination. With each trait or characteristic added to the requirements, the number of persons meeting the desired conditions becomes smaller in a given total population. For example, there are many twelve-year old children in the United States but only a fraction of them live in New York City; only a fraction of the twelve-year olds living in New York City are in the ninth grade in school; a still smaller number of

twelve-year old New York City ninth-graders are boys; still fewer twelve-year old New York City ninth-grade boys are taking technical courses; and an even smaller number of twelve-year old New York City ninth-grade boys in technical courses have intelligence at the genius level.

When homogeneity is attained in one trait or in a small number of characteristics for a group of persons, heterogeneity is certain to exist for most other traits or characteristics. There is, therefore, no possibility of obtaining a group homogeneous in general, but only of so selecting a group that its members all satisfy at most a few desired conditions.

Range of talent, or variability, refers to the degree of homogeneity or heterogeneity existing among a group of persons with primary regard to the effect upon test scores. For example, pupils in the fifth grade might be expected to score within certain limits on a general achievement test, but the limits within which pupils in the fourth, fifth, and sixth grades might be expected to score would be considerably further apart. In general, correlation coefficients are lower when the range of talent or variability of the group is small than when it is large. (See CORRELATION.) Similarly, reliability coefficients (See RELIABILITY), which are merely special applications of the coefficient of correlation, are smaller when the groups of pupils are homogeneous than when the groups of pupils vary more widely in important traits or characteristics. J.R.G.

HOMOGENEOUS GROUPING — See CLASSIFICATION OF STUDENTS.

HONOR SYSTEM. An agreement by students to assume major responsibility for keeping their conduct within the bounds of accepted morality. Applied most commonly to examinations, the honor system allows teachers to leave the class without proctors. Infractions are reported by students to their own disciplinary board. The use of honor systems is more common in colleges than in secondary schools.

Although the honor system has been used

HONORS COURSES — HOUSE PLAN

as a means of developing desirable character traits by encouraging the students' sense of responsibility and by appealing to the desire for social approval rather than fear of punishment by the teacher as the basis for good behavior, the honor system has not been without its critics. As usually employed, the honor system has not paid sufficient attention to the assumption of responsibility by the individual student. As these critics point out, all that the introduction of the honor system has done in many instances is to substitute a roomful of student proctors for a single teacher proctor, a change that may have little significance for character education unless it is accompanied by a realization by each student of his own responsibility for his personal behavior. Moreover, the students who constitute the court which usually tries offenders rarely have the understanding or the maturity which is needed if they are to participate effectively in the reeducation of the student who has abused the confidence of his teachers and his classmates. The honor system is, therefore, no universally applicable aid to character education; its educational value depends very largely on the school's readiness and ability to use the opportunities it presents for stimulating the development of the students' character. G.E.H.

HONORS COURSES. In English universities honors courses, which require a relatively thorough study of one field for a student's entire college career, are distinguished from "pass" courses, which require much less thorough study of several subjects. Although a few American colleges offered honors courses in certain fields previously, Swarthmore College drew nationwide attention to them when it developed them successfully beginning in 1922. Today more than one hundred and fifty American colleges offer them in one or more fields. They are characterized by their enrolling only students of high ability, and often also by relatively individualized instruction, infrequent class meetings and examinations, a long term of a year or two, concentration upon one field of study, and the use of examiners from sister colleges.

The chief advantage seen in honors courses is that they "break the lock-step" and permit able students to be taught faster and more than do traditional courses. They have also

led the way not only toward experimentation in curriculum and examination, but especially toward freer, more truly individualized instruction. The latter contributions are obviously of permanent value.

Some dissatisfaction has arisen over the relatively narrow specialization in honors courses, a feature which may be avoided to some extent if a student takes honors work for only part of his time along with the study of two or three other fields. Most criticism, however, has been concerned with the principle of segregation of the able students. Such segregation tends to emphasize doubtful standards of worth, as well as extrinsic incentives which many educators believe should be minimized. (See LIBERAL ARTS COLLEGE.)

HORIZONTAL ORGANIZATION OF SUPERVISION—See SUPERVISION OF INSTRUCTION.

HORMIC PSYCHOLOGY — See PSYCHOLOGY, SCHOOLS OF.

HOUSE PLAN. The house plan is modeled after the "college" plan of English universities. Exemplified chiefly at Harvard and Yale, where "houses" were made possible by the gifts of Edward S. Harkness, it breaks a large college into smaller units, in which students are more likely to feel a community spirit and to have access to a full round of college activities. Each house is a connected series of residence halls for several hundred students. In order to have a distinct community spirit, the houses are usually grouped around quadrangles, with but few outside entrances. Each house is equipped with a dining hall, a library, lounges, faculty quarters, and perhaps a garden. It may also own space and equipment for athletics.

The plan has been notably successful. Surveys have shown that many more "house" students than others associate intimately with faculty members; attend intellectual discussions; use a library daily; and take part in social affairs, inter-house athletic contests, and other extra-curricular activities. Such

results may be partly due to the attractiveness of the houses and to the practice of scattering the members of a fraternity in several houses so that they seldom segregate themselves. The plan seems to have few, if any, disadvantages if students are encouraged to become acquainted with the college as a whole through campus-wide courses and functions. Its chief benefits seem to be available to almost any college which can make its dormitories somewhat isolated and largely self-supporting. (See LIBERAL ARTS COLLEGE.) M.G.F.

HOUSEHOLD ARTS—See HOME ECONOMICS, TEACHING OF.

HUMAN GEOGRAPHY—See GEOGRAPHY, TEACHING OF.

HUMAN RELATIONS, COMMISSION ON (Progressive Education Association). This commission was established in 1935 by the Progressive Education Association. Its primary objective was to study ways and means of helping young people and their parents to gain a better understanding of some of the problems of human living which exist in the modern world, and to attempt to reveal the motivating forces underlying certain types of human behavior. The studies also included the impact of the various social institutions upon the individual and the consequent effects upon human relations and behavior.

The activities and contributions of the commission can be grouped in three general categories: (1) the publication of a series of books, (2) the production of a series of motion pictures, and (3) the presentation of two series of radio programs, relating to the problems of group living in a democracy.

The books published by the commission are intended for use by teachers, parents, and students. The content of several of the books consists of problems growing out of the changing needs of youth, the place of the family in the development of desirable social relationships, and the function of various institutions and areas of knowledge in the establishment of better understanding among individuals and groups in a democratic society.

The production of a series of motion pictures grew out of a project started by a committee of the Motion Picture Producers and

Distributors of America, which asked the commission to take over and extend the work begun by the committee. The commission selected from regular motion picture production those scenes and sequences which would best serve as examples of typical human relationships. The scenes were then organized into separate films, or units, to be used for educational purposes. Over fifty excerpts were made, covering a wide range of human behavior from the time of early childhood to maturity, and representing many of the types of relationships an individual would encounter in the course of a lifetime. *The Human Relations Series of Films* is described in a catalog published by the Commission, containing synopses, sample student discussions, student reactions to the use of films, and a preface of human needs.

One series of thirteen radio programs was presented by high school students on the American School of the Air program sponsored by the Columbia Broadcasting Company, and consisted of discussions of typical human relations problems. In 1938 another series of programs was presented. This was a full year of broadcasts on *Frontiers of Democracy*, and was also a part of the American School of the Air series. These programs dealt with some of the basic social and educational problems of our time and discussed such topics as housing, the use of science, juvenile problems, education in a democratic as compared with a totalitarian state, and the contributions youth can make to the solution of social problems.

The commission accepted the basic concept that if young people are to function democratically they need an education that will assist them in solving those problems which concern them most directly. These problems are usually related to, or grow out of, the relationship with other individuals or groups in our society. With the increasing complexity of our social structure and organization, students need to know more about the motivating forces of human behavior and activity, in order better to adapt themselves to changing conditions. Since democracy is essentially a plan of human relations, youth should be guided in such a way that they develop better ways of relating themselves to others. The values of democracy should be stated in terms of the welfare of individuals and groups. To achieve success in effect-

tive human relations is to further the cause of democracy itself. The commission through its activities has attempted to indicate ways in which these objectives may be realized.

HUMAN RELATIONS, INSTITUTE OF—See POST-DOCTORAL EDUCATION.

HUMANISM. The educational movement known as humanism derived its initial impetus from the revival of learning during the Renaissance. This renaissance does not mean that learning in the preceding period had been in a state of suspended animation but rather that the new education stood in sharp contrast to it. While the older education had been authoritarian and preoccupied with the supermundane, the new education was really a rebirth of classical learning with its spirit of inquiry and its greater emphasis on mundane affairs. Genetically, then, the spirit of humanism is older than its name. But even the name had historical roots, for humanistic education referred to a renewed interest in that type of education which classical times had noted for its *humanitas*, an education which befitted man in all his dignity, in short, a liberal education.

Although liberal in conception, humanistic education soon developed an indigenous form and content, the significance of which is not spent even in the twentieth century. Because what classical culture had to contribute on the physical, moral, and intellectual development of man was locked in a purer Latin than the corrupted form preceding the Renaissance and even more securely locked in Greek, which was almost unknown in Italy at that time, humanistic education inevitably became identified with a study of these ancient tongues. Indeed, these two languages are often referred to as "the humanities." It should not be surprising, therefore, that humanistic education became literary in character, and that it aimed at taste and elegance

of style. This æsthetic influence, however, was greater in Italy than north of the Alps where the humanities were studied as instruments of social and religious reform as well.

Offshoot of liberal education though it was, the humanistic spirit was not welcomed at first in the medieval university where up to this time the study of the seven liberal arts had centered. Consequently, it was necessary to establish new schools where the new learning might flourish. These schools, known as humanistic schools, became rivals of the universities and ultimately the pattern for European and American secondary schools. It is from this historical root that Latin, and, to a less extent, Greek have received nourishment in secondary school curricula right down to the twentieth century. The typical method of instruction in humanistic schools was the prelection so highly developed by the Jesuits in their humanistic *ratio studiorum*.

While at its best, humanistic education aimed at *sapiens atque eloquens pietas* (wise and eloquent piety), at the physical, æsthetic, social, and intellectual as well as the moral and religious development of man, at its worst, it became a narrow study of language alone. Not only did it become restricted to literary form but, at the depth of its degeneration, it became a study of the style of one author, Cicero, so that even to this day "Ciceronianism" is a title of reproach. Furthermore, so narrow and even disciplinary did it become, that the Latin grammar school which taught the humanities in English speaking countries came to teach little more than what its name implies.

In the seventeenth century, an attempt was made by the humanistic realists to rescue humanistic education from its narrow formalism and to base the study of the humanities again on the substance they could contribute to the contemporary life of the time. The movement, however, did not widely affect the schools. A strong neo-humanistic movement at the end of the eighteenth and in the early nineteenth centuries put stress on recapturing for the schools not so much the languages of antiquity as the free spirit of inquiry so notable in Greek culture.

But the major attention in the nineteenth as well as the twentieth centuries has been focused on the contest which humanism has long waged with naturalism. The point at

issue has been whether literary or scientific studies are of greater importance in a liberal education. The division of studies into human and physical, however, has resulted in a dualism difficult to resolve. It is preferable, some say, to realize that the rapid growth of such social sciences as anthropology, economics, and sociology are developing a body of materials which will not fit under either of these headings because they connect man's life with natural conditions. Therefore, the schools should be concerned with the common background in which humanistic and naturalistic studies are united.

This close union of humanism and naturalism also demands mention of the fact that in the twentieth century some associate humanism with the self-sufficiency of man and his independence of the supernatural. Thus pragmatism (*q.v.*), the philosophy underlying much progressive education, goes by the name of humanism in some quarters.

HUMANISTIC REALISM—See **REALISM**.

HYGIENE AND HEALTH EDUCATION. Health education is the process of instruction in the preservation of those qualities enabling individuals to live a full, satisfying life physically, mentally, and emotionally. This definition carries us beyond the realm of many of the narrower concepts often held and recognizes the child as an individual with a complicated system of mutually dependent organs.

It is upon such a philosophy that curricula in health education and hygiene are developed and goals established. Such programs include instruction in all phases of physical, mental, and emotional health. Scientific information is given in the preservation of health through its personal application to the individual. This phase of health education is called *personal hygiene*. In order that the

student may apply his knowledge to his everyday living experiences he must be acquainted with the hygiene of all the organs of the body. This implies a thorough understanding of the anatomical and physiological backgrounds and the functioning process of the organs.

Community hygiene includes instruction in the health program of the community; how it is promoted and maintained so that it contributes most to the welfare of each individual and to the community as a whole. In essence this is the responsibility of public health departments which are concerned with such matters as preventable diseases, including those that are acutely communicable, venereal, and of a tuberculous character; the hygiene of the individual including maternity, infant, pre-school, and school hygiene; and general and specific sanitation.

Industrial hygiene has assumed greater significance during recent years. It is the science of the preservation of life through the study of health hazards in industry. In general this involves problems of building sanitation, safety education, and industrial diseases.

School hygiene has come to mean the health implications of building location and construction; heating, lighting, and ventilating; construction of the school program to avoid health hazards; general safety; and sanitation.

The term *sex hygiene* and *social hygiene* are too frequently used synonymously. Sex hygiene is the science of living healthfully for the purpose of reproduction. Social hygiene is the science of living healthfully with one's associates. This has broader connotations than sex relationships. It might involve tuberculosis, scarlet fever, or pediculosis. At the same time the term *sex hygiene* is somewhat limited in that it does not take sufficient account of boy and girl relationships outside of actual reproduction implications. It might be better to employ both terms, namely, *sex hygiene* and *social hygiene*, provided that each is used in its distinctive meaning.

Hygiene and health education are both closely related to physical education. It is quite generally accepted, in fact, that the health and physical education program in school systems should be combined under one administrative head. Physical education makes

HYGIENE AND HEALTH EDUCATION

a definite contribution to the organic vigor and neuro-muscular development of the individual. Furthermore, it offers splendid opportunities for mental and emotional health through its varied program of sports and games. It offers individual help in health through corrective exercises and orthopedics under the guidance of proper medical authorities.

Health education has not advanced as rapidly as have some other phases of education in testing and measuring the results of health programs but progress is being made. Until quite recently physical education teachers who have usually been the ones charged with the responsibility for conducting health programs have had little preparation for this work in teacher training institutions. This situation is rapidly being remedied. It is reasonable to expect that with improved teacher preparation will come better school health programs, properly organized and administered, and scientifically evaluated.

Health education as an integral part of the school curriculum: Health education is often referred to as a school subject. This is erroneous. Health education is not a school subject but a part of the general school curriculum inextricably interwoven in the pattern of the child's everyday living experiences. It should neither be departmentalized nor compartmentalized.

The physical health of the child is promoted through healthful school living, health service, health instruction, and wholesome physical activities. Healthful school living presupposes a school environment that allows for scientific heating, ventilating, lighting, cleaning, and safety measures; a school organization that fosters a hygienic program of instruction giving due consideration to schedule making, rest periods, school lunches, individual differences, and time allotments; provision for the services of specialists who can examine students and detect health conditions that need correction; and a teacher-pupil relationship that promotes a sympathetic and understanding attitude on the part of the teacher concerning fatigue, discipline, physical examinations, follow-up work and the correction of remediable defects, and protection against communicable diseases.

All of these relationships to the health of the child have definite educative implications.

The school health education programs fails unless it makes full use of all health related aspects of the school curriculum in organizing its instruction. Having embraced these opportunities to improve the health knowledge, habits, and attitudes of the child, the school organizes health instruction as follows:

Elementary school health programs include indirect, incidental, correlative, and direct instruction. Direct instruction is given only in proportion to the elementary school child's capacity for assimilating factual knowledge. The program is built around the child's everyday living experience and is not developed merely to supply health facts.

The junior high school follows the same general plan with increased emphasis on direct health teaching. Since many children leave school at the completion of the ninth grade, they should have an adequate amount of scientific health knowledge to live successfully and happily in their community.

The problem of health instruction in senior high schools is more difficult than on the two lower levels. Ideally if the program has functioned successfully in the elementary and junior high schools the senior high school student should be in a position to appraise his own health needs intelligently and, with sympathetic guidance, to attain his health goals. Such a Utopia has not as yet been reached universally largely because of inadequate teaching personnel, inadequately trained teachers, and economic factors beyond the control of the school. The health counselor or health coordinator plan seems to be the best so far devised but is operative only where there are a well-trained person, adequate school funds, and unlimited community resources for the correction of physical defects.

"Health lectures" on the gymnasium floor are ineffective. Anatomy and physiology classes with but few exceptions do not meet students' health needs adequately. Interest wanes because hygiene courses often duplicate material covered in home economics, biology, chemistry, and physics. Individual guidance under a skilled health coordinator seems to bring results but, as stated, the obstacles in the way of inaugurating such a program are often times insurmountable. (See also HEALTH.)

I. Q.—See INTELLIGENCE QUOTIENT.

IDENTICAL ELEMENTS—See TRANSFER OF LEARNING.

IDENTIFICATION. Identification is the process of envisaging oneself as playing the rôle of someone else and sharing vicariously in his success and prestige. It is the tendency of identifying oneself with the objects, persons, or organizations of one's admiration and interest for the purpose, conscious or unconscious, of gaining security, recognition, and power; and becoming like those whom one respects and admires. The young son may identify himself with his father, whom he regards as a wonderful person. This serves as a powerful stimulus toward emulation of the father. In his play the child identifies himself with the rôle he enacts, be it teacher, preacher, doctor, engineer, or racketeer. The adolescent acquires a feeling of superiority by identifying himself with an exclusive club or fraternity or his school. The hero of the novel, movie, or daydream often is conceived as the subject himself.

While the process of identification may be a harmless indulgence, it often proves to be one of the most important factors in the child's cultural development in that it will stimulate him to emulate the worthy patterns of conduct and achievement of superior persons. On the other hand, it may prove a detrimental influence in that the individual may imitate low patterns of behavior; he may be satisfied with mere imaginary achievements; and he may use the mechanism as a substitute for action, or as a retreat from reality, as in the daydream. IDIOT—See MENTAL DEFICIENCY.

ILLITERACY. The exigencies of war ordinarily focus attention on educational inadequacies. Among the problems of general concern in 1917-18 was that of illiteracy, and it was again brought to the fore in 1940 through the refusal of the Army of the United States to draft men having less than fourth grade education. These latter in the age group 18-44 numbered 1,458,540 or 5.3 per cent in 1940. According to the 1930 census 4,283,758, or 4.3 per cent of those 10 years of age and over had no education whatever.

Figures based on previous schooling or on a statement of ability to read and write inadequately reflect the size of the literacy problem. Education varies in quality from region to region and schoolroom to schoolroom, and no measure of childhood education is ever an adequate index of adult needs. A simple statement of ability to read and write is a measure of technical skill but not of functional capacity. Various literacy tests have been devised, some for voting; but to date there has been no satisfactory test of functional literacy, and thus no statement of the problem.

Although the narrow demands of war create the emergency which brings literacy into focus, the latter is really more important to peaceful social living, and should be of primary consideration in preparing the people of the United States for intelligent participation in the post-war world. The smooth functioning of every society depends partly on the tools that the society forges for developing the individual's understanding of his fellows. The compact tribal community had no need of any tool except conversation. But today when the community is 2½ billions of people the tools must of necessity yield rich and full vicarious experiences. It is common to point to newly developed instruments of

communication as having brought the people of the world closer together. Awareness has been mistaken for understanding, as is attested by the World Wars of the 20th century. Until the radio and motion picture—or perhaps some yet undeveloped media—have been perfected, they will stand secondary to the printed word as effective tools for use in understanding one's fellows.

In the United States there have been two movements designed to cope with illiteracy. One is the literacy or elementary education movement concerned primarily with foreign born adults, but with opportunities for study ordinarily extended also to the native born. Classes in elementary English for adults (under a variety of names) have been supported on a state-wide basis by more than half of the states, and by a good number of local communities. Part of the funds appropriated for adult education under the various Federal emergency acts of the 1930's have been devoted to literacy classes. Although elementary education for adults has existed in the United States since the time of the colonial evening school, it has been emphasized only since the first world war.

The other movement which was planned to develop functional literacy is even more recent and is still in the embryonic stage. This is the move to simplify reading materials so that those adults with limited knowledge of the tool subjects may still be socially literate. A few simplified books have already been published, and experiments are going forward at the Readability Laboratory at Columbia University.

Both of these movements, though excellent in their way, must be considered as stop-gaps. On the one hand, there are many pieces of literature, particularly in the sciences, which cannot be simplified without losing brevity and precision of definition. On the other hand, there is a grave question whether it is not wasted time and effort to develop language skills in men and women who have no formal education. As a rule, adults who have not yet mastered the mechanics of the reading process when they enroll in elementary classes rarely master language skills well enough to read easily. This failure is due

not so much to decline in mental ability as to lack of adequate motivation for the sustained effort that is necessary for learning to read. Language skills whether in conversation, reading, or writing are mastered more easily if periods of practice are short but regular in occurrence. A reading lesson a day is ordinarily essential for most effective teaching. Adults usually do not have this time to devote to school, and their learning suffers. Furthermore, they are using valuable time which ought to be given to consideration of those social problems which can be solved only by mature men and women.

Certain of the South American countries have met the problem of their illiterate masses by adult education which dispenses with printed instruction and uses instead lecture and demonstration. This system has proved extremely effective in meeting the urgent need of Indian populations for instruction in such subjects as modern hygiene, scientific agriculture, and community planning. Ingenious as it is, it is recognized by those who use it only as an emergency measure, for any such scheme is valid only so long as leaders of integrity are in power. Every democracy must eventually face the necessity for creating a social vigilante out of every member of society.

Granted that perfecting the tool of literacy to the point of functioning in the modern world is preferable to any process of simplification of reading materials or literacy education, then adult literacy in the United States comes within the province of the elementary school teacher of children and the adequate support of public education. The problem of the illiterate Negro and poor white of the South, the Spanish-speaking person of the West, and the farm population of all states is that of Federal support for education (*q.v.*), which will be apportioned according to ability and effort of the states to support education. This leaves only the foreign born illiterate as the special charge of the adult educator. The ideal adult school of the future is one in which a working knowledge of the fundamentals will be assumed of all the native born, and men and women in the school may devote their time to use of those fundamentals in acquiring greater social skills.

Statistics on Illiteracy:

U.S.A.: Census of 1930— 4.3% of total population
 10 yrs and over
 1.5% of native whites
 9.9% of the foreign born
 16.3% of Negroes

Comparison with earlier years (Total Population
 10 years and over.)
 1870.....20.0
 1890.....13.3
 1910..... 7.7
 1920..... 6.0
 1930..... 4.3

Ranges by States

(Total population 10 years and over.)

<i>Lowest</i>	<i>Highest</i>
Iowa 0.8	South Carolina 14.9
Washington ... 1.0	Louisiana 13.5
Oregon 1.0	New Mexico . 13.3
Idaho 1.1	Mississippi .. 13.1
Utah 1.2	Alabama 12.6

Foreign Countries:

(According to *Department of Commerce Foreign Commerce Yearbook, 1936*).

NOTE: Definitions of illiteracy vary among other countries.

Brazil:	70% (estimated)
Chile:	25% (estimated in 1930)
Denmark:	practically none
France:	7% (unable to read or write over 5 years of age, 1931)
Italy:	21% (unable to read over 6 years of age, 1931)
Japan:	10% (excluding children under 7)
Mexico:	54% (estimated in 1934)
Netherlands:	practically none
Spain:	43% (unable to read or write over 10 years of age, 1930)
Sweden:	practical none

ILLUMINATION — See **LIGHTING, SCHOOL**.

IMBECILE—See **MENTAL DEFICIENCY**.

IMITATION IN LEARNING AND TEACHING. Whether we look at children or whether we look at adults, we see that people sometimes imitate those around them and sometimes they do not. Sometimes this imitation is conscious and deliberate, the actions of the other person forming a model after which the individual wishes to pattern himself; at other times the imitation is unconscious, a form of incidental learning. The person picks up the same attitude, fear, prejudice, enthusiasm or gesture, as someone with whom he has been in contact. As teachers, we are interested in determining how we can get children to imitate certain patterns and to refrain from imitating others. We

also want to determine whether imitation is a good technique to use as a deliberate method of instruction.

Imitation is dependent partly upon the ability to perform the act that is to be imitated. Though parents continually coax infants to imitate certain words and movements, the children make no imitative response until they have reached a certain age, a certain degree of maturation.

Once the ability to perform is present, even if only to a very slight degree, attempts to attain a better duplication of an observed behavior will ensue, provided the achievement of that response is the child's goal. An observed pattern of response becomes the learner's goal if he connects it with the satisfaction of some one of his motives. He may do as others do because he likes them and because he wants to be like the people he likes; he may do as others do because he envies their prestige and desires to attain similar prestige himself; he may do as others do because that will get him affection from the person he imitates or from some other person who has shown a liking for the qualities of the "model"; he may do as others do because he desires that specific achievement or trait; he may do as others do because doing the same thing together is fun. Social motives and motives of mastery thus form the context in which imitation is deliberately used in learning.

There are occasions when imitative response seems to be almost a reflex action. Speech—both inflection and grammar—is so much affected by the speech of daily associates that many a parent has been counseled to move to another neighborhood if he wishes to change the speech pattern of his children. Such unconscious imitation is most effective when the pattern of response is not yet firmly set. In most instances this means in early childhood. As the child matures, the patterns he has already acquired interfere with the automatic imitation of others, and often also with the success of deliberate imitation.

Imitation which is not deliberate need not be reflex or automatic. Certain other conditions favor its occurrence. When a child reflects the fear of his mother, he is not imitating her in the narrow sense of the word. Her sign of fear teaches him that the stimulus is a dangerous one and so he, too, re-

IN LOCO PARENTIS

sponds with fear. A similar pattern operates with regard to a large number of the prejudices of his group which he acquires in time. There is also the adoption of certain rationalizations which he has heard adults make as excuses for certain behaviors. These are sometimes adopted with full knowledge of what they are, but usually there is no such understanding and deliberate calculation.

So far as most skills are concerned, deliberate imitation is necessary for good learning; in the field of attitudes deliberate imitation is a negligible factor. The teacher must guide herself accordingly and set up such school situations that only desirable imitation will occur.

The question remains whether, in those cases where it is possible to teach a skill through imitation, this pedagogical technique should be employed. If teaching through imitation means setting up a model for the child to try to attain, then this is nothing more than making his goal clear for him, a desirable feature of teaching. In learning to speak a foreign language or in developing certain manual skills, the very closest imitation of the model is desired. It is in the creative arts, including thinking, that the unwise use of imitation may rob the learner of his ability to create. Here the work of another person should not be used as something to copy, but as something to learn from and to adapt to one's own ideas. Besides its frequent use in areas where more initiative on the part of the learner should be allowed, imitation has been abused as a pedagogic procedure by requesting the learner to duplicate step by step features of a response which has never been presented to him as a whole. Being led through the procedure in such a meaningless manner produces little real learning, unless the learner by his own efforts manages to perceive the pattern of what he is doing.

Another danger that the teacher must watch out for is that children become "dependent imitators" so that they match their conduct to that of others not because they have figured out that the technique the other person is using is one that will bring them to their own goal, but that they have learned to use the other person (a specific person or a class of persons) as a cue for their own behavior, with the general feeling that these others will lead them in the right direction.

This follow-the-leader trait can be seen in the negative also, that is, a certain person or class of persons take on the characteristic of those not to imitate.

In fascist countries, dependent-imitation is a trait that teachers do everything they can to develop, and the rewards and punishments of the social environment reinforce this learning. In a democratic country such behavior should be maladaptive. It is maladaptive to the maintenance of democratic conditions. Unfortunately, the schools as well as the general social environment often set up conditions particularly conducive to such dependent behavior. Its legitimacy in the case of the mentally retarded is obvious. But it is too often used in the teaching of art, literary, and music appreciation where professional critics become the cue for judgment rather than emotional reaction or a set of standards. The same attitude is often developed with regard to the appraisal of government and prospective political policies. Schools have been particularly prone to train children to make their judgments of truth and falsity match those they see in print.

Imitation in the sense of learning from others and from models, even exactly copying them in some instances, is a method which has a legitimate place as a means of saving much time by allowing the accumulated knowledge of generations to be acquired by one individual in his lifetime. However, it is inconsistent and dangerous to encourage dependent-imitative behavior. B.B.F.

IN LOCO PARENTIS. The relationship of the school system, and particularly of its teachers, to its pupils is known by the legal doctrine of *in loco parentis* (in place of the parent). Legally as well as factually, the school (and the teacher) has the responsibility of the parent for the welfare of the pupils entrusted to its care for the period of schooling. This *quasi*-parental relationship is basic to many of the responsibilities and powers of the teacher. It places upon the teacher the responsibilities of a careful and prudent parent for the protection of the pupil (See NEGLIGENCE)

This doctrine also accounts for the author-

ity of a teacher to administer corporal punishment to pupils. With the exception of New Jersey and the District of Columbia, corporal punishment may be administered to students in substantially all the other states, subject to the power of individual school boards to impose other restrictions. Needless to say, such corporal punishment has limits: it must be for valid reason, must be administered in a manner and under circumstances commensurate with and appropriate to the wrong in question; it must not be of unreasonable severity or unduly punitive and harsh; and it must be administered only and solely for the proper education of the errant pupil or for the preservation of necessary school discipline. The existence of such power on the part of school teachers can derive only from the teacher's status *in loco parentis*; it is subject, as is a parent's right of corporal punishment, to criminal penalties for excess; and a teacher may also be subject to civil suit for recovery of damage, if the punishment be excessive or beyond the permissible realm of a teacher's activity.

The *quasi*-parental relationship has also been of value in affording legal justification for the school safety patrol where operated in the absence of specific statutes, in that the school may legally operate off its premises so as to care for the welfare and safety of the pupils in transit to and from school, an obligation which falls upon the school because it is *in loco parentis*. As the temporary parent, so to speak, the school under such circumstances may be under the obligation to protect the life and guard the physical welfare of its student body, since obviously that would be the rôle of the child's natural parent.

That the school should be held to the responsibilities of a *quasi*-parent is of utmost importance to parents. Their children, in most cases, are compelled to attend school. If the school could not be held to the accountability of a reasonably prudent and careful parent, our entire structure of compulsory free public education might suffer.

A significant aspect of the doctrine of *in loco parentis*, for schools, is the possibility that the doctrine may condition the scope of a school board's power. Since it places upon the school and teachers the responsibilities of a careful and prudent parent for the protection and furtherance of the inter-

ests and welfare of the pupils, an extension of the meaning of the doctrine *in loco parentis* may lead the school to the point, for example, of regarding as an essential part of its task the administration of periodic health examinations with a view to remedial treatment as well as mere diagnosis; in fact, some schools have already interpreted their duties as broad enough to require them to provide clothes, food, shelter, and otherwise unobtainable equipment for the pupils. If it is *in loco parentis*, the school will assume functions which may not seem obvious at first glance, functions which it may once have been impossible to contemplate out of the home. Personality adjustment, vocational guidance, job placement, physical fitness, family adjustment, home visiting, and family life-education are but a few of these more recently adopted school functions based on a broader conception of the rôle of the school in our society. Others include such activities as adult recreation, vocational retraining and rehabilitation, consumer education, nutrition education, and the host of other community activities on the periphery of the programs of progressive school systems. Inevitably as the school branches out into newer fields, and assumes functions which at other times and in other communities have been regarded as parental functions, the doctrine of *in loco parentis* assumes wider proportions. In terms of this concept it is, then, possible to think of the outer circumference of the circle of influence and power of the school as being delineated by the outer limits of applicability of *in loco parentis*. Just what these outer limits are will vary with the *mores* and customs of the time and place, as well as with the economic and political beliefs of the period, and will yield to these urgent social justifications which are acceptable to the people. Nothing could be further from the truth, therefore, than to ascribe a rigid and inflexible meaning to the doctrine *in loco parentis*.

A possible danger must be observed in this broader view of *in loco parentis*, in that the doctrine may become an instrument of oppression in the hands of a school board seeking to exercise powers endangering the civil rights of pupils and others. H.N.R.

IN-SERVICE TEACHER EDUCATION
—See TEACHER EDUCATION; TEACHERS' WORKSHOP.

INATTENTION—See **ATTENTION**.

INCENTIVES. Numerous studies of incentives have been undertaken predominantly for the purpose of determining whether reward, punishment, or rivalry will produce the fastest learning and the most effort in the undertaking of various tasks. Much less attention has been given by educators to the possibility of developing desirable incentives as part of satisfactory personality growth. Anthropologists—Margaret Mead, for example—have pointed out, however, that incentives, such as competition, gain their power not only from their relation to the biological needs of man but also from their position in the culture pattern in which that man finds himself. Recently dissatisfaction has been expressed with the assumption that all children of the same age and intelligence respond similarly to the same incentives. It has been found that the effect of school marks varies with the level of aspiration of the pupil who obtained them so that a mark of 90 may bring the feeling and incentive of failure to one student while a mark of only 70 brings a feeling of success to another. Moreover, since the same student's aspirations are not similar in different achievement areas, rivalry may be more of an incentive for him in one field of attainment than it is in another. The amount of ego involvement in the task influences the effect which competition produces. Children of different personality patterns have also been found to respond differently to the same incentive. Thus, young, nervous, or excitable children often do worse in a task when competition is introduced. Moreover, the context in which the incentive is set is also a factor. The findings of several studies, for instance, are that public reprimand or sarcasm brings different results than do private reprimand and private sarcasm. The immediacy with which the praise, blame, or the reward is bestowed also affects the learning or the amount of work done.

Studies comparing the effects of reward and punishment have on the whole shown rewards to be a more efficacious incentive though in some instances punishment is sometimes the stronger motivator. It has been found that although material which has little meaning is sometimes learned more quickly when punishment for failure is introduced, forgetting sets in rapidly and amounts

to a greater degree than when punishment is not involved in the learning. The comparative effects of reward and punishment continuously applied to people over a long period of time have not been studied under experimental conditions. Observation of life situations has shown, however, that though there are individual differences in the degree of punishment to which a person can "stand up," long-continued punishment eventually causes a breakdown of personality in one or more of its phases.

When the problem of incentives is considered more broadly under the problem of motivation, it is seen that the force of an incentive will depend upon its relation to all the motives present for that individual in the specific situation. As an individual grows, he develops a set of values which have motivating power for him. These values or a large number of them become set into a stable hierarchy. A low-ranking value can have strong force in a situation where no higher motives are in competition while a motive high up in the hierarchy may lose much if not all of its incentive value if a still higher motive is in competition with it in the same situation. Punishment, set up as a negative incentive to deter a person from carrying out a certain act, may be looked upon as a barrier or difficulty which must be overcome to attain the goal. Thus the punishment meted out to those who "cut" classes in high schools may be interpreted by some students as a challenge to their ability to absent themselves from a class without being detected. In such cases punishment does not produce any of the guilt feelings and emotional disturbance which it so often entails when it is felt by the one being punished as a sign of social disgrace.

Another area of motivation to which too little attention has been paid is the extent to which incentives will hasten insight into problems. Incentive studies have dealt mainly with memoriter learning, and with speed of tasks the performance of which is already known. Maze learning problems do present a task which the animal or child cannot yet perform. However, the extent of the problem is the learning to go here and not to go there, with the "here" and the "there" already placed before the animal. In these cases the error is easily seen as the wrong direction to the goal which is also the incentive. Cer-

INCENTIVES

tain incentives or rewards at the end of the maze produce faster learning on the part of the animal than others. With human beings, too, one finds that the more attractive the reward gained when the solution is gained the faster the elimination of wrong responses in those situations where there is some means of determining which response is wrong (even when it is punishment which indicates the error).

An important question for teachers is whether extraneous incentives will hasten insight into a task where the correct response is not just one to be chosen from among a number all set out in front of the learner and all of which he can already perform. If the task is one where the solution must be contrived rather than selected from obvious alternatives, then will that solution be hastened if it is known that some reward will be offered if the solution is contrived or some punishment meted out if it is not contrived within a specified time? Furthermore, will competition among a group of rival learners hasten insight?

Experimental evidence is meager for such situations. Many progressive schools are going on the theory that in such cases greater insight will come about through interest in the solution of the problem itself. They doubt the effectiveness of extraneous incentives which are tacked on to the situation by someone but which do not themselves arise as a consequence out of the contriving of the solution. Taking their lead from John Dewey's monograph on "Interest and Effort in Education," these educators advocate a curriculum based on children's interests as a solution to the problem of incentives. One of the great advances in the understanding of motivation has been the finding that the same objective incentive not only has different effects on different people but that it is actually a different incentive for different persons. Thus, when rivalry is introduced into a situation, the goal for each individual is not necessarily the mere attainment of greater achievement than that of some of the others or all of the others involved. If there is a specific reward offered, the competitor may actually be interested in attaining the reward rather than in beating the other fellow. The other competitors form barriers to his attainment of the reward. Whether or not a specific reward is offered,

there may be a number of other rewards and punishments involved in the competitive situation as it is experienced by the different rivals. For one child the competitive situation means the necessity of maintaining status when this is difficult to do, for another it means the possibility of gaining status, for a third it means the public exposure of lack of ability. For one child it means that success will bring added affection from his family, for another child it means that again his group will cast him out on the fringe because of their envy. Where to one child his position in the group is but an indication of his degree of skill in a situation where he has no other way of measuring the quality of his work, another child measures his skill strictly in terms of his rank among others, and accepts no other sign of success but that of outdoing his neighbor. For another child several of these motives operate together.

There are some educators who are fearful not that rivalry for high marks will fail to motivate their students but that such motivation may be too effective. In other words, the incentive of getting the highest grades may become the most dominant, if not the only, incentive for working hard. When school years are over, this usually leads to lack of interest in any further study since the main motive has been removed. It is therefore recommended that the building of worthwhile interests be the main form of producing motivation for learning, that commendation be for good work done and for improvement rather than for high rank in the group, and that children, far from being urged to rival their fellows be helped to feel satisfied with their best efforts even when these bring inferior results.

Many educators object to the excessive appeal to incentives which do not grow out of the learning experience itself. These critics regard the educational experience as consisting of more than facts and skills to be mastered by employing any incentives that prove to be effective. To them the most desirable incentive is the one which results from the pupil's recognition of the significance of the material being studied and of his need for mastery. They, therefore, look to the improvement of the curriculum and the methods of teaching as affording the necessary incentive to improvement. Even these critics, however, do not object to appealing to in-

INCREMENTS — INDEPENDENT STUDY PLANS

centives which improve the pupil's personal adjustments or even to the use of such incentives as controlled competition when no other appeal is available for a topic that must be studied. (See MOTIVATION.) B.B.F.

INDEPENDENT STUDY PLANS. Independent study plans are a belated attempt (primarily since the first World War) on the part of the college to provide for individual differences, especially as represented by the needs of the superior student, who should have the amount and type of work that will provide the materials and personalities to stimulate maximum development of his capacities. Earlier and more general development of individualized methods of instruction has been retarded by relatively large enrollments and classes, as well as by the expense of independent study procedures. Large classes usually mean a common or general instructional pattern, within which are provided occasional adaptations of materials or methods to individual needs.

An increased awareness of the intellectual needs of superior students, and a desire to break the academic lockstep of time to be spent and credits to be earned have contributed to the development of a variety of independent study plans. In general, individual plans provide for: considerable freedom with respect to class attendance, independent reading and study under guidance, individual and small-group conferences, special problems or papers, and comprehensive examinations.

Where tutors or preceptors have been provided, their functions are to aid students on an individual basis or in small groups with classwork, examinations, correction of dis-

abilities, and development of special capacities and interests. Their functions and activities should be much broader by way of guidance than merely to see that students pass the courses.

Honors work is intended as a stimulus to superior students of the junior and senior years of college, and usually calls for specialization in a particular department and a program of independent reading culminating in a comprehensive examination (*q.v.*) at the end of the college program. Guidance is provided on an individualized or tutorial basis and in small groups, with emphasis on mastery of a subject rather than on mere fulfillment of the limited requirements of a single compartmentalized course. It is expected that this procedure will help to coordinate ideas from several fields and to break down barriers between departments of instruction. Somewhat like the reading program of the honors plan, some colleges suspend class attendance for certain periods of the year, before and after holiday recesses or at the end of academic terms, to permit uninterrupted reading and study.

Higher institutions have used a variety of other instructional procedures in an attempt to meet individual needs, with emphasis on independent study: individual conferences, small discussion groups, seminars, excursions and travel, individual study during vacations, and periods of work or study in community activities. Independent study at the graduate level is represented by thesis problems, seminar reports, and laboratory, field, and clinical projects. A few colleges have attempted to explore the interests and experiences of the student as a starting point for selecting an appropriate program of study, including extracurricular activities, which places considerable responsibility on the student in selecting a program of study, in planning and carrying out his work, and in evaluating outcomes.

The limited number of experimental investigations available indicates that individualized projects and reading programs, and other independent study plans, have demonstrated their effectiveness in comparison with more conventional instructional procedures. Independent study plans are relatively expensive, but should pay ample dividends in terms of stimulation of the intellectual life

INDIA, EDUCATION IN

of superior students; indeed, such procedures may prove helpful in the instruction of all students of serious purpose. Other possible values of these innovations lie in the intellectual challenge to faculty members and the breaking down of departmental lines. C.V.G.

INDIA, EDUCATION IN. The problem of education in India is highly controversial. In the seventeenth century Robert Knox wrote of the Sinhalese: "Their ordinary Plowmen and Husbandmen do speak elegantly . . . there is no difference between the ability and speech of a Country-man and a Courtier." In 1881 Sir George Birdwood wrote of the Indians that "Our education has destroyed their love of their own literature . . . their delight in their own arts and, worst of all, their repose in their own traditional and national religion. It has disgusted them with their homes—their parents, their sisters, their very wives. It has brought discontent into every family so far as its baneful influences have reached." This condition stems from the premises on which Western education was developed in India. The two primary ends in view were (1) to convert Hindus and Musalmans to Christianity and (2) to provide a personnel for the lower branches of the Civil Service. In so far as a sense of duty and more idealistic ends were also envisaged, these were largely vitiated by the conception of a superior civilization to be imposed on others for their own good. The principle that the only way to educate is "to find out what people have been trying to do, and help them to do it better" (Ruskin), or that "systems of government should be extensions of the culture of the peoples concerned" (T. M. Heron) was not followed. As a result of Lord Macaulay's influence, supported by that of Lord Bentinck, it was decided in 1834 to form a class of persons "Indian in blood and colour, but English in tastes, in opinion, in morals and in intellect." The English Orien-

talists who had held with Jonathan Duncan in 1792 that the purposes of a Hindu university should be to recover and foster "the most ancient and valuable general learning and tradition now existing perhaps on any part of the globe" were ignored. The power of those who held with B. H. Baden Powell, who, as late as 1872, could write "In a country like this, we must not expect anything that appeals to mind or deep feeling" determined Indian educational policy until far into the nineteenth century.

Education in India has too often been treated (as above) as if education had been unknown. Actually, universities (Taxila, Nālandā, Nadiā, Totagamuwa, etc.) had existed in India since a time before the beginning of the Christian era, and these had been centers of practical as well as theoretical instruction. Innumerable schools of various kinds, ranging from Sanskrit colleges to village schools for elementary teaching, all self-supporting, existed in the nineteenth century, and some of them still survive. Vocational instruction was provided for by apprenticeship.

The whole subject is complicated by the differences between the educational ideals of native India and those of the Western world. Literacy, for instance, is less of a problem to a culture based on highly developed oral traditions. The "illiterate" Indian peasant may be considered "uneducated" according to Western standards, yet because of his extensive oral knowledge of a great traditional literature he is not to be so considered according to Indian standards. Where the Western world proceeds on the assumption that education is primarily in knowledge, the Indian assumption is that education should be in understanding. The Indian considers it fundamentally important to preserve the Indian respect for learning; the relation of discipleship that attaches the pupil to his master; and the Indian view that we do not know a book by reading it, but only when we know it by heart—(a phrase that means much more than mere rote memory, and implies the deepest kind of understanding).

Even more important is the fact that the traditional Indian education, whether theoretical or practical, has always been based upon a definite conception of the purposes of life; while it is just the lack of unanimity

on this fundamental point that explains the eclectic quality of modern Western education.

Before 1835 British educational policies had hardly affected any area outside Bengal. A succession of Universities founded after the Mutiny (1857) were at first purely examining bodies, teaching being given only in colleges of all sorts and conditions. The first Universities were those of Calcutta, Bombay, and Madras. The beginning of the great Muhammadan University at Aligarh dates from 1871; that of the Universities of the Panjab and Allahabad from 1882 and 1887. Colleges for the sons of Rajput noblemen were founded at Ajmer and Kathiawar. In 1901 reforms were instituted by Lord Curzon and the conversion of the Universities to teaching bodies and centers of culture was begun. Some attempts were made to encourage the vernaculars and to give practical instruction in engineering and agriculture. Of the younger Universities for which Indians have been primarily responsible, the Hindu University of Benares is by far the most important.

But, as remarked by Mr. Mayhew, "the educational systems established by the British and India have never been a natural or free expression of national life." That, indeed, could hardly have been the case where "all affiliations and disaffiliations of colleges were to be finally determined by the (foreign) government; all professors, readers, and lecturers must be approved by it." Higher education has been given, moreover, almost entirely in English; this imposes great handicaps on the Indian student who is expected to do all his thinking in a foreign language, and with whom the foreign teacher cannot communicate in his own. These conditions are, of course, being progressively remedied as the control of education passes into Indian hands, though a generation of Indian students ignorant of their own history and culture has already been produced. Where Indians have gained control of educational institutions the growing tendency has been to relate curricula once more to the geographical and psychical environment in which they are to serve, and also to revert to vernacular instruction, making English a second language and giving to it what is considered its proper place, not as the vehicle of teaching but as a *lingua franca* and a means

of communication with the Western world. One of the most remarkable institutions is the college of the Arya Samaj known as the Gurukula, where the curriculum is designed to cover a period of some twenty-five years, and all the students can speak Sanskrit freely by the time they are twelve years old.

The proportion of the national income spent on formal education is very small. The number of university graduates in 1938-9 was 21,658. Out of a total population of 352,837,778, that year, 28,138,856 were literate, 23,969,751 of these literates being males, and 4,169,105 females. A.K.C.

INDIVIDUAL DIFFERENCES. The educator's concern with individual differences is related to the need to adjust the curriculum in such a way that each student develops to the maximum of his ability and grows into a well-rounded person. Individuals differ in the degree to which they possess almost any characteristic that can be named and in the total pattern of their personality. It is customary to apply the term individual differences to traits which can be separated sufficiently from the total personality to be measured. Since methods of measuring human traits have been improved, it has been possible to determine how individuals vary with respect to almost any trait. It has been found that with respect to most characteristics, the population as a whole, or a large unselected sample of it, distribute themselves along a

INDIVIDUAL DIFFERENCES

scale of that trait from a relatively small possession of it to a relatively large quantity and that the nearer we approach the average quantity that is possessed the more persons there are who possess the trait to that degree. In other words, most human traits, distribute themselves approximately according to the *normal probability curve* (*q.v.*).

Because it has been found so often that measured variations among human beings do resemble the frequencies of a rough normal curve, the working assumption has been adopted that all traits actually are so distributed in every random sample of the population. Frequently tests are considered invalid if they do not bring about results which have a normal frequency distribution. The same is said of the teacher's grading of essays and other performances where quality must be judged. The expectancy that every small group will show a normal distribution is of course a fallacious deduction from the hypothesis of normal distribution since the normal distribution assumes a large, unselected group and not a small group of people. From time to time, however, experiments show that the hypothesis of normal distribution for the population at large may itself be an overgeneralization, and that some abilities and other traits actually show a J-curve, U-curve, or a skewed distribution.

Since abilities develop in time and are not given full-fledged at birth, any factor which operates on a large group to place a barrier to further development at a relatively low standard of attainment will skew the distribution of that attainment and may even bring about a break in the distribution. It is obvious, for example, that the distribution of reading ability among adults will be *partly* dependent upon the educational opportunities afforded those adults. In social attitudes and behaviors, it has been noted that the pressure of social conformity may produce a J-curve, with the majority of persons piling up at one end of the distribution. In cases where the population is divided into two groups with social pressures in each of the groups driving in opposite directions, a U-curve will result, the individuals piling up at each end of the distribution leaving few in the middle.

It is not only the distribution of individual differences and the effect he can have upon that distribution, but also the range of indi-

vidual differences and the effect he can have upon that range that is important to the educator. The range of reading ability at age eight for children who have had two years of training will be much smaller than the range of reading ability at age sixteen for children who have had ten years of training, and this will hold true even if reading teaching is adjusted to individual needs. Adjusting the school program to individual differences in no way implies that individual differences will be reduced. They are just as likely to be increased, since there is also a wide variation in the ability to profit from teaching and experience.

The organization of rapid, normal and slow learning classes is the attempt to group children according to their ability to profit from instruction. (See CLASSIFICATION OF STUDENTS.) The difficulty of such organization is two-fold. In the first place, a person's ability to profit from instruction differs in different subject-matter areas. In the second place, it is difficult to find a good index of the ability to profit from instruction. Even in any one learning area, the ability to profit from instruction is a function of the C. A., the M. A., the I. Q., the present achievement in that area, specific aptitude in that area, knowledge in other areas which will have a transfer effect on this one, various factors of motivation and health, as well as the method of instruction. Since each of these factors itself changes at different rates and in different ways, even a multiple index cannot be a permanent index. Adjustment of the curriculum to classified groups of children rather than to individual children is therefore not sufficient to take care of individual differences. Whether there has been ability sectioning or not, heterogeneity rather than homogeneity is characteristic of school classes. Children within a single school class as well as within a single school grade tend to differ more widely among themselves than they do on the average from grade to grade, and the range of both their abilities and educational achievement may extend from grade levels two or three years below to a like amount above. The exact extent of these differences will vary according to the nature of the trait considered. It will tend to be less with respect to those traits and abilities which are given greater weight in promoting children

from grade to grade, and greater in traits of less immediate concern to the functioning of the school and its manifest objectives.

Various provisions for individual differences other than, or as well as, ability sectioning have been suggested and put into practice by educational authorities, some of these being designated by the names of the authors or of the school systems employing them. Examples are the Dalton, the Winnetka, and the Morrison plans (*q.v.*). "Job sheets" or "unit assignments" which are placed in the hands of each child and followed by him at a rate commensurate with his ability provide for individual rates in school progress, though not for individual interests. Standardized remedial exercises are also employed to suit the needs of the particular pupil, usually after standardized diagnostic testing. If the deficiency cannot be remedied in this manner, the child may be assigned to an "adjustment teacher" or to one teaching an "ungraded" class, whose special task is to remove the deficiency by individual attention and to return the pupil to a graded class as early as possible. (See SPECIAL CLASS.) School systems sometimes include research or personnel divisions which are concerned with the individual study of widely variant pupils and appropriate recommendations to their teachers. Guidance (*q.v.*) services are also occasionally available so that the student may have special help in planning both his educational and vocational career.

A broader attempt to adjust the school to individual differences has been made by "progressive" educators. These educators have moved away from the conception that adjustment to individuals means helping them keep pace with the group or the mere lowering of age standards for the mentally slow and retarded. They have taken individual adjustment to mean adjustment to individual *needs*. The child's ability to progress faster or further is not the only consideration. The needs of the able and gifted children receive as much consideration as the needs of the dull and the normal. (See GIFTED CHILD, EDUCATION OF.) Varying interests also play a major role. While no set pedagogic technique has been adopted as the one best procedure, the courses of study in these progressive schools are necessarily much more flexible and adaptable to individual needs than any of

the differential curricula adopted in schools that are organized on the basis of ability grouping. The common denominator for the various children attending a school consists of values, and generalizations, and conceptions, and broadly named skills and appreciations to be improved in year after year. The specific content may vary widely, provided that through it the objectives are reached. Different individual assignments and group projects with division of labor allowing for individual differences are both used. A distinctly different emphasis from the more traditional ways of adjusting to individual differences is that not only are individual differences allowed for, but variability is encouraged.

INDIVIDUAL PSYCHOLOGY — See PSYCHOLOGY, SCHOOLS OF.

INDIVIDUALIZED INSTRUCTION.

Providing learning experiences which make it possible for the pupil to proceed by himself without help from the group and very little help from the teacher is the aim of individualized instruction. The learner progresses by individual study instead of through group discussion, class recitation, and the question-and-answer method. Favoring individualized instruction are those educational influences which stress individual differences, the futility of the "lock-step" in education, and the right of the pupil to advance at his own rate.

In school systems or classrooms where individualized instruction has been emphasized, as in Winnetka, Illinois, detailed work books and job sheets have been prepared, often by groups of teachers, giving the steps and directions in full. At least four preliminary steps are basic to planning this type of instruction: first, the objectives must be clear and definite; second, activities needed in attaining the standards or objectives must

INDOCTRINATION

be carefully outlined and finely graded; third, self-corrective practice tests must be supplied for the pupil's use; and fourth, mastery tests for the teacher's evaluation of the degree of attainment of standards must be available. The standard of attainment is the same for all pupils, and whenever a pupil reaches the standard he proceeds to the next block or division of the work. A standard in arithmetic may be the mastery of the one hundred addition combinations, or a part of them, within a certain time with a hundred per cent accuracy. As a rule, the pupil is taught how to budget his own time. Usually the plan is confined to the tool subjects; it does not extend to physical education, games, dramatics, clubs, and other socialized activities.

Several serious criticisms of individual instruction have been raised. The plan means "mediocre" achievement for some pupils because the standards must be lower than the possible achievement of many bright pupils. It provides primarily for individual differences in rate of learning, but it misses the values resulting from socialized class activities inherent in meaningful, life-like applications of the so-called tool subjects. The social development of many pupils lags behind their intellectual advancement, and accelerated pupils who get into older groups may become maladjusted socially. Too much "predigested" material makes pupils too dependent; the "spoon-fed" ones fail to develop ability to think, to plan, to work out their own salvation.

Individualized instruction, of course, is not a question of all or none. Every good teaching procedure utilizes individual effort to a greater or lesser degree. The directed study idea, the laboratory technique, and the Morrison Unit Plan with its assimilation period all stress individual instruction. The daily assignment followed by pupil study and preparation demands individual effort. These procedures, however, usually do not require detailed instruction and directions found in work books; they provide for discussion and other group activities; and the teacher plays a prominent rôle in these oral activities. Moreover, provision for individual differences should be made through enrichment, as well as through individual progress at one's own rate. As with any other plan of instruc-

tion, the individual instruction idea has been modified to meet new conditions and to serve in remedial teaching. (See DALTON PLAN.)

INDOCTRINATION. Two questions, often confused, are here considered: the proper meaning of the term indoctrination and the proper attitude toward inducing uncritical belief.

The term has a long history, and during the years several distinct usages have developed. Originally, to indoctrinate was to implant doctrines. Later, since implanting doctrines was the main purpose of the medieval school, to indoctrinate and to teach came to mean about the same thing. In this teaching there was the implication—alike from the customary school practice of the time and from the meaning of the word—that the teacher's aim in indoctrinating was so to implant the doctrines he taught that they would remain fixed.

With the Protestant Revolt each side through its schools used this indoctrination as a conscious device to fix its doctrines permanently in all it could reach. Under such conditions the indoctrination by "our" side of "the right" doctrines was right and praiseworthy, while the indoctrination by the other side of its "wrong" position was not only wrong as to intended result but was also wrong as to the process used, since this took advantage of the helplessness of youth.

From the eighteenth century onwards there has come, with the stress first on the individual and later on rapid social change, an increasing demand that education develop individual initiative and fit youth for democratic responsibility and for resourceful adaptiveness amid change by teaching the young people increasingly as they grow older to think critically and decide responsibly, each one for himself. Accordingly, there is increasing rejection of the inducing of uncritical belief as unfitting the student for practical life

amid rapid change and as an unethical denial of respect for personality.

The present status as to the meaning of the term and the respective support given to the several usages seem to be about as follows:

1. The oldest sense is that indoctrination is simply the teaching of ideas with no implication either as to method used or as to approval or disapproval of either process or result. This meaning was until recently the recognized literary usage; in fact the Oxford English Dictionary (this part issued about 1900) carries no other meaning.

2. Several diverse groups among us agree in approving the uncritical implanting of ideas in the young as a proper means toward ends counted as important. These groups tend then to approve the term indoctrination to describe this kind of education. Among these supporting groups are (a) certain churches, especially those which stress absolute doctrines; (b) certain groups which advocate revolutionary social reforms; (c) certain conservatives who wish to resist threatened social change; (d) certain "patriotic" groups—with not a few educators joining in—who fear critical study lest it fail to train the rising generation adequately in the cultural inheritance including the proper patriotic outlook.

3. A group of American students of education, especially, and others influenced by them, who stress democracy and adaptability to change, reject the inducing of uncritical belief in youth as prudentially unwise and morally wrong. These people use the term indoctrination only in a bad sense to describe and denounce this (to them) wrong kind of teaching.

4. Intermediate between groups (2) and (3), and often difficult to distinguish from them, are certain who inconsistently use the term to denounce, for example, Nazi indoctrination, but themselves favor an analogous uncritical implanting of democracy in our youth, even using the term to describe their approved home practice.

5. An unexpected (by this writer) use of the term indoctrination appears in our (temporary) naval training schools. This "naval indoctrination" is said to include "instruction in the fundamentals of military discipline, naval customs and usage." No special stress on doctrines appears.

The foregoing analysis of the present status of indoctrination is based in good part on a study of over 300 instances of the use of the term indoctrination taken from the writer's reading the past four years, not selected but including all the pertinent instances found. Of these by far the largest number, from one-half to two-thirds, seems to support the derogatory sense (3) with its rejection of indoctrination; about one seventh of all support sense (2); slightly fewer accept sense (1), while exactly eight instances support sense (5) and even fewer admit to (4). W.H.K.

INDUCTIVE METHOD. The inductive method leads to the discovery of generalizations or uniformities: principles, laws, rules, and definitions. Its basic meaning in education is the same as in the natural and social sciences. Copernicus, Newton, and Darwin are classed among the inductive scientists because they laid bare some basic generalizations that describe the operations of nature. That teacher is teaching inductively who leads his pupils to rediscover these same principles in mathematics, physics, biology, grammar, and other subjects.

The inductive approach requires (1) the recognition of a problem, suggested by puzzling data (e.g., What has produced our apparently endless varieties of plants and animals?); (2) the gathering of instances (of changes in plants and animals, in this case) by observation, experimentation and reading; (3) the formulation of hypotheses or tentative explanations that might account for the changes; (4) the testing of these hypotheses by checking them against the instances; (5) the formulation of the accepted hypothesis or explanatory principle; and (6) the further verification of this principle by applying it to instances as widely different as circumstances permit. In school, verification is usually satisfied by reference to authorities.

The inductive process is correlative with the deductive process, which supplements and completes it. When we face a puzzling instance, such as a peculiarly shaped flower, and explain it by a specific principle of natural adaptation that is known to us, we are proceeding deductively. What is called problem solving in school involves deductive problems almost exclusively.

INDUSTRIAL ARTS EDUCATION

The steps of the deductive procedure may be listed as follows: (1) get the conditions or problem clearly in mind; (2) recall known facts or gather facts that may apply or serve in the solution; (3) choose the facts or generalizations that appear most likely to apply or account for the situation or conditions (tentative inference); (4) try out the proposed solutions or apply facts (evaluation of tentative hypotheses; (5) formulate inference or state answer or conclusion; (6) verify or check conclusions.

Pupils should be shown the significance of both the inductive and deductive procedures in solving particular types of problems, but this should be done through experience in solving problems rather than by having the pupils learn a set of steps which they are to try to apply later. It is valuable for pupils to learn to recognize and to apply these steps as means of improving their ability to think through problems and to plan solutions.

The deductive procedure is used most frequently by pupils in mathematics and science classes in the solution of examples and problems involving the application of principles or rules. In actual practice the pupil should be taught (1) to get his problem in mind—what is given and what is required, (2) to select the best plan for solution that is suggested by the facts, (3) to solve the problem, if possible, and (4) to verify or check results. In case of failure to solve the problem, the student should check the first step and then repeat the other steps until a solution has been obtained.

The Herbartian method-whole, with its five formal steps, embodies this inductive-deductive procedure. In the first step, *Preparation*, including the three phases of review, aim, and motivation, the student's mind set is oriented toward the new material. The specific instances are presented in the second step, *Presentation*. The third step, *Comparison*, aims at getting the students to see the fundamental similarity underlying all the instances, a similarity that is formulated by the pupils in the fourth step of the lesson, *Generalization*. The fifth step, the *Application*, is a deductive activity in which the students apply the newly discovered principle to other illustrations.

The Herbartian method, though not so

popular as it once was, can still be used effectively by teachers whose interest in the type of pupil thinking that is stimulated is greater than their devotion to the specific steps of the method-whole. Used wisely, the method is appropriate for helping students to understand a basic principle (e.g., that a modifier must be placed near the word it modifies). The weaknesses of the Herbartian method lie in the ease with which the teacher can dominate the lesson, in the excessive phases of the method rather than to the outcome, and to the apparent simplicity of a formula that can be used in all subjects regardless of its applicability.

In life situations, the solution of problems involves a combination of inductive and deductive methods. There is no pure inductive and deductive procedure—there is no deduction so rigid that is not modified, however, slightly, by experience, nor is it possible to have an induction based solely on observed phenomena without touching upon known laws or principles. Modern scientific method uses both procedures as the requirements of the problem indicate, and uses them not as distinct steps but as interrelated phases of problem solving.

INDUSTRIAL ARTS EDUCATION.

Industrial arts education is a phase of practical arts education (*q.v.*) which emphasizes mechanical or manufacturing types of activities. It is the modern version of what was formerly called by such names as *manual training*, *manual arts*, and *mechanic arts*. Industrial arts may be divided into (a) elementary industrial arts, usually given in grades 1 to 6 inclusive, and (b) industrial arts at the secondary school level, given as a rule in grades 7 to 12 inclusive. In many progressive school systems industrial arts education is compulsory for boys in grades 7, 8 and 9, and optional in grades 10, 11 and 12. It is becoming increasingly available on an elective basis to girls in junior and senior high schools. When given in the

school, it is taken by both boys and girls and is given by the "regular" teacher. In junior and senior high schools, industrial arts is taught by specialists.

The dominant purposes of industrial arts education at the secondary school level are given in the following twelve objectives formulated by the Committee on Standards of Attainment in Industrial Arts Education of the American Vocational Association:

"1. To develop in each pupil an active interest in industrial life and in methods of production and distribution.

2. To develop in each pupil the ability to select wisely, care for, and use properly the things he buys or uses.

3. To develop in each pupil an appreciation of good workmanship and good design.

4. To develop in each pupil an attitude of pride or interest in his ability to do useful things.

5. To develop in each pupil a feeling of self-reliance and confidence in his ability to deal with people and to care for himself in an unusual and unfamiliar situation.

6. To develop in each pupil the habit of an orderly method of procedure in the performance of any task.

7. To develop in each pupil self-discipline which requires one to do a thing when it should be done, whether pleasant or not.

8. To develop in each pupil careful, thoughtful work without loitering or wasting time (Industry).

9. To develop in each pupil an attitude of readiness to assist others when they need help and to join in group undertakings (Cooperation).

10. To develop in each pupil a thoughtful attitude in the matter of making things pleasant for others.

11. To develop in each pupil a knowledge or understanding of mechanical drawing, the interpretation of conventional and working diagrams.

12. To develop in each pupil elementary skills in the use of the more common tools and machines in modifying and handling materials, and understanding of some of the more common construction problems."

These objectives are attained by having school instruction given in one of several ways—in general shops, a series of unit shops, and in variations of these. (See GENERAL

SHOP, PRACTICAL ARTS EDUCATION, and UNIT SHOP.)

The range of activities in industrial arts education varies greatly. From the simple work in elementary industrial arts, through the more advanced activities at the junior high school and senior high school levels, pupils have the opportunity to try out many kinds of materials, tools, and processes. Clay, textiles, leather, wood, metals of many kinds, and plastics are used.

At the junior high school level, drawing, woodworking, electrical work, printing and other graphic arts, and metalworking are among the activities most frequently found. Work in aeronautics and radio is increasing rapidly. Starting with simple and safe tools, the learner soon becomes familiar with an extensive variety of tools, including in the upper grades many sorts of power-driven tools and machines—a fit introduction to the power-machine-air age.

Materials, tools, and processes are but means leading to a better understanding of man's vast occupational activities and of the progress that is being made in using natural resources for the benefit of man. It appears reasonable to hope that through well directed industrial arts education students will attain a deeper appreciation of the dignity and nobility of labor and the joy that comes to him who works creatively.

The objectives of industrial arts are attained by merging the fine arts and the industrial arts, and by combining good design, proper choice of material, and superior manipulative work.

INFANT CARE. Instruction in infant care has been developed chiefly in connection with health programs carried on by both public and private agencies. Individual and group instruction for expectant women and mothers of infants is given by physicians and nurses, often in special centers for maternity and infant welfare. To some extent similar opportunities are open to fathers. A variety of pamphlets and bulletins can be obtained from government agencies such as the Children's Bureau of the Department of Labor, as well as from private consultation services. Preparental instruction for younger women and girls, usually including practical experience in caring for infants, is offered by some health agencies, as well as by schools and colleges (see PREPARENTAL EDUCATION). The Children's Bureau and the United States Public Health Service have considerably extended the facilities for instruction in infant care, particularly in rural areas.

Although the original purpose of instruction in infant care was the reduction of infant mortality, it has more recently broadened its scope. As scientific information regarding infant development and the significance of attitudes acquired in infancy has increased, instruction in infant care which deals with psychological as well as physiological factors has been offered by certain agencies. This expansion fills a real need, since most programs of parental education (*q.v.*) do not reach parents of children younger than nursery school age.

INFORMAL TEST—See STANDARDIZED TESTS.

INHIBITION. *Inhibition* denotes partial or complete interference or suppression of one function or activity by another function or activity. In the stammerer, speech may be inhibited by the fear of stammering. Gastric secretions may be inhibited by anger. Anti-social impulses may be inhibited by social ideals. The child's spontaneity may be congealed by sarcastic cuts, and his boisterousness and expressions of anger inhibited by threats or expressions of social disapproval. The rule is that stronger impulses tend to block weaker ones. Painful or shame-producing experiences tend to be inhibited by being dismissed from the mind or by being repressed. Most serious inhibitions that the child forms are probably caused by deep-seated conflicts between his egoistic, emotional drives and the taboos and prohibitions of society.

Many inhibitory adjustments of anti-social proclivities are wholesome and necessary, and much to be preferred to unbridled license. But excessive or unwise inhibitions may produce paralyzing suppressions, block initiative and spontaneity, create mental conflicts (*q.v.*) and maladjustments, and lead to the formation of injurious mental complexes and compensations (*q.v.*).

Conditioned inhibitions are the result of specific processes of conditioning. A child may seize, take hold of, or handle a cat. If the animal bites or scratches the child, this experience will inhibit subsequent desires and actions to repeat the performance. Thus the experience of being bitten or scratched when the child takes hold of a cat may produce a conditional fear of cats, (See PHOBIA) and inhibit any subsequent tendency to handle or fondle these pets. Many inhibitions

are the result of specific processes of emotional conditioning.

Reciprocal or *mutual inhibition* occurs when two tendencies are about equally strong. These two tendencies will then extinguish each other, resulting in postponement, inaction, or a state of vacillation. Thus the student may vacillate between the desire to play tennis and the necessity of completing the term paper.

In *retroactive inhibition* later formed associations may impair those formed earlier. Recent learning may alter, inhibit, or impair earlier ones. The challenge of imminent danger may inhibit the tendency to run. If a series of facts is learned in the order a—b—c, the attempt to learn them in the order a—b—z may weaken the older association to a greater extent than mere inactivity.

INSECURITY, EMOTIONAL — See MENTAL HYGIENE.

INSTINCT. In its modern form, the once widely accepted instinct theory holds that both man and many animals exhibit certain relatively complex forms of behavior, or relatively specific motivational tendencies, which are wholly or in large part innate in their respective species. Among the frequently suggested criteria of such unlearned modes of response, or instincts, have been their supposed universality within a given species, their peculiar adaptiveness to its environment, and their appearance without opportunity to learn them. Proponents of various formulations of the instinct theory—James, McDougall, Thorndike, Woodworth, and many others—have differed widely in their inventories of human instincts, but among those commonly listed, food-getting, curiosity,

fighting, acquisitiveness, rivalry, and parental behavior have been typical.

Controversy over the existence of such human instincts—especially vigorous in the 1920's—has been complicated by the use of the term instinct with a variety of specific meanings. Two general concepts of instinct, however, have tended to predominate in modern discussions of the topic. (1) Using the term in the general biological sense common since Darwin, many writers (e.g., Thorndike, Loeb, and Watson in his earlier writings) have viewed instincts as unlearned sensorimotor responses of a certain type. These responses—presumed to be most clearly exemplified by such activities as the mating, maternal, and nest-building behavior of many animals—have usually been defined as more complex than the simple reflexes, largely inherited by a given species, and evoked by certain determinate stimuli without prior learning. Writers conceiving of instincts in this fashion have differed as to the degree of their complexity and modifiability by learning; quite commonly these responses have been regarded as unlearned chains of well-coordinated reflexes, and have been differentiated from simple reflexes on the basis of their greater complexity, indefiniteness, and modifiability. (2) Other modern writers, however, have preferred to define instinct teleologically, i.e., in terms of an end or purpose. For these writers (e.g., McDougall, and in large measure James, Thorndike, Woodworth, and Tolman) instincts are primarily innate propensities or dispositions that impel an organism toward certain unlearned and often relatively specific goals, such as are involved, for example, in mating, acquiring, or seeking the company of one's fellows. These ends have been variously described by different writers in biological, mentalistic, and behavioral terms, but from the general standpoint in question, common emphasis has been placed on instincts primarily as instigators to goal-directed activity.

At present, the technical use of the term instinct with reference to human behavior is largely restricted to psychoanalytical writings. Avoidance of the term by academic psychologists is due in part to its ambiguity, but chiefly to the present widespread reaction against the instinct theory. Some psychologists would even discard the traditional con-

INSTITUTE OF THE BROTHERS OF THE CHRISTIAN SCHOOLS

cepts of instinct altogether for various reasons, including doubt of their explanatory value, and of the validity of the distinction they imply between "innate" and "acquired" forms of behavior. Even when retaining some concept of instinct to deal with certain activities of infra-human animals—as many contemporary psychologists do—most of these writers tend to the view that there is adequate evidence for the existence of few, if any, human instincts. Certain human responses (i.e., the reflexes and the initially undirected physiological motives often termed primary "drives" or "needs") are commonly regarded as unlearned; but evidence derived chiefly from studies of child development and of cultural influences on man's reactions has led to widespread doubt of the instinctive character of most of his more specific motives and complex forms of behavior.

That human beings are organisms with certain characteristics at birth, characteristics which influence the kinds of characteristics (including the kinds of thoughts, feelings, and behaviors) that each will display during his life is almost universally accepted. Much of the controversy over the instinct theory boils down to the question of whether that concept properly explains the kind of influence that this is, and whether certain so-called instincts are in fact instincts as these have been defined above. Since the term has acquired so many unacceptable connotations—unacceptable in the light of present knowledge—many psychologists believe it the wiser policy to drop the term *instinct* completely.

Unfortunately, it is just these fallacious connotations of the term which teachers and parents often accept as working hypotheses in their relations with children. They are inclined to feel that "instinct will tell them what to do," or that the child has a bad instinct which the adult can do nothing to eradicate, or that children have certain specific instincts which always respond when they are appealed to. At one time teachers talk about "letting their reason get the better of their instincts", as if that were a bad procedure and instinct were more dependable than reason, while at another time they assert that you cannot change human nature. Though it is true that parents and teachers constantly display behavior towards children which signifies that they do believe that human nature

is modifiable, nevertheless their confused beliefs with regard to "instincts" enter, on many important occasions, into their technique of guiding the young. Though it would be disastrous for parents and teachers to believe that any baby can be turned into any kind of person desired by the trainer (a claim that was put forth for a time by some behaviorists), it is equally disastrous for parents and teachers to believe in a fixity of characteristics where no such fixity exists. INSTITUTE FOR CHILD GUIDANCE

—See CHILD GUIDANCE CLINICS.

INSTITUTE OF THE BROTHERS OF THE CHRISTIAN SCHOOLS.

The Institute was founded in 1680 by St. John Baptist de La Salle, then Canon at Reims, France. The Founder's interest in popular education led him to organize a group of schoolmasters so as to provide free Christian instruction for the poor. Members of the Institute take the three usual vows of obedience, chastity and poverty, and also bind themselves to remain with the society permanently and to devote their efforts always to the free instruction of the poor. They accept the direction of any kind of male educational instruction. The Rule organizing the Institute as a regular religious society was drawn up at Rouen in 1705 and was approved by Benedict XIII in 1725. It fosters unity of action, apostolic zeal and adaptation to new circumstances. The provisions of the Rule have made it possible for the Institute to undertake in many lands such diversified educational activities as conducting schools of agriculture, trades, engineering, and commerce; normal schools, orphanages, reform schools, trade unions, study circles, boarding schools, colleges, benevolent societies, and elementary and secondary schools.

Many educational reforms may be attributed to the leadership of St. John Baptist de La Salle. Under his direction the Brothers

INSTRUCTION SHEETS

introduced the so-called method of "simultaneous instruction," providing for the group instruction of children of the same intellectual development. It replaced the individual method then in use. This innovation led ultimately to the formation of sections in classes. Another innovation was teaching pupils to read the vernacular before beginning instruction in Latin. A method of teaching was developed which was made available for general use in the schools of the Institute through a manual entitled "Management of Schools." The manual was prepared by the Founder and the most capable teachers of the Institute and presented the method and principles developed during a series of conferences extending over a period of years. Everything done in school from the opening until the closing hour was dealt with in detail, so as to provide for thoroughness, coordination, uniformity and effective teaching. The interest in better methods of teaching finally led to the founding of the first normal school, established in Paris one hundred years before the French Revolution. Late in the eighteenth century, just before the French Revolution, there were 121 houses in France and six abroad, comprising a total of 1,000 Brothers and 36,000 pupils. The program of the Institute met with popular approval, yet the Brothers were soon deprived of the right to teach in France. The decree of 1791 required all religious teachers to throw off the authority of Rome through taking the civil oath. The Brothers refused to take the oath, as a matter of conscience, and were compelled to abandon their schools. Two Houses continued to exist in Italy. They furnished refuge for the members expelled from France. The dispersal was a serious blow and practically destroyed the work of the Institute.

The Brothers were permitted to return to France by Napoleon in 1802. The program of the Institute again prospered. During the period between 1833 and 1933 new foundations were established in Europe, North and South America, Asia, Africa, and Australia. During the term of office of Brother Philippe, Superior General from 1838 to 1874, over one thousand new Houses were established, of which 726 were in France and 276 abroad. Teaching by Religious was abolished in France in 1904. Almost 1300 establishments of the Brothers were closed between 1904 and 1908.

The Mother House is in Rome. A Superior General and a Council of Assistants administer the affairs of the Institute. The twelve Assistants represent the interests of the sixty-three provinces or districts in the five continents in which the Brothers control schools. The latest report (1938) lists 14,435 Brothers caring for 323,077 students in every quarter of the globe. There are five provinces in the United States: Baltimore (1845), New York (1848), St. Louis (1849), San Francisco (1868), and New Orleans-Santa Fe (1918). Seven colleges, 56 high schools, 22 elementary schools and eight special institutions require the services of 1,560 Brothers to care for 33,166 students (1942). (See ROMAN CATHOLIC EDUCATION.) INSTRUCTION SHEETS. From the educational point of view an instruction sheet is a device that will assist a student or trainee to learn. In practical arts and vocational education several types of instruction sheets are used. Each derives its name from the function it is designed to serve.

Assignment sheets usually give lesson assignments. This may call for both theory and practice. *Information sheets* commonly give information that is related to the so-called practical work. To illustrate, an information sheet may deal with the topic "How shellac is made" or "How to do arc welding."

Operation sheets deal with a specific operation or group of related operations, as for example, "How to use a bench jointer," "How to grind a lathe tool," or "How to sharpen a circular saw." The preparation of operation sheets for operations that occur in a variety of jobs simplifies the task of preparing job sheets which then need not include detailed information that is available on the operation sheets.

Job sheets, as used in schools, usually contain all information essential to efficient performance of the job. They may also contain

INSTRUCTIONAL TEST — INTEGRATION

questions and references for related study. Job sheets, as has been mentioned, may be simplified by referring to information sheets and operation sheets. Job sheets for advanced workers may take the form of blue prints and specifications.

Instruction sheets of various kinds are used in industrial establishments as well as in schools for training purposes. In order to avoid the possibility that an instruction sheet, such as a job sheet designed for training purposes, might be mistaken for a job sheet used in industry for production purposes, some industries label all of the instruction sheets — assignment, information, operation, and job sheets—*Information Sheet or For Information Only*.

Work Sheets. This term may be used for any sheets of whatever nature that contain the data needed for the work to be done. For example, an operation sheet, a job sheet, a detail drawing, or an assembly drawing or blue print may each be a work sheet. F.T.S.

References.

R. W. SELVIDGE, *Individual Instruction Sheets* (Manual Arts Press, Peoria, Ill., 1926).

W. H. MAGILL, *Administering Vocational Education* (Educational Publishers, Minneapolis, 1941).

INSTRUCTIONAL TEST. A test employed as an integral part of the teaching of a unit is called an *instructional test*. It may be used as a pretest to determine the initial status of the group. It may be used also to motivate learning, to locate weaknesses requiring remedial instruction, and to provide needed practice.

Since the instructional test is a teaching aid more than an instrument for measurement, the construction and administration of such a test is largely the responsibility of the teacher rather than of the research worker. The content of the test is determined by the subject matter the class has been studying instead of the type of research that precedes the construction of a standardized test (*q.v.*). The length of the test reflects not the need for achieving statistically reliable scores but the desirability of including as many questions as are necessary to cover the important skills and facts which the student is expected to have learned as he studied the unit. Although the students' scores do represent a measure of their achievement, the teacher is more concerned with the ways in

which the test results indicate weaknesses and misunderstandings that must be corrected. Instructional tests may be administered at any point in the term's work that seems most appropriate, but they are used most frequently at the end of a unit of work.

Because the purposes to be served by instructional tests are related so closely to the procedures in each separate class, there are few published instructional tests. [*The Sangren-Reidy Instructional Tests in Arithmetic* (Public School Publishing Company) are illustrative of the published instructional tests.] C.C.R.

INSTRUMENTALISM. The philosophical theory which, based largely on biological evolution, conceives of mind or intelligence as the means whereby the organism makes its adaptation to the environment, is usually known as instrumentalism. Hence, to judge educational practices of method and curriculum from the view of their efficacy in achieving individual and social aims has also gone under the title of instrumentalism. J.S.B.

INSURANCE, TEACHERS' — See **TEACHERS' INSURANCE.**

INTEGRATION. Integration is the process by which an individual improves the functional unity of his experiences. It is the way in which he brings himself as a total organism into increasingly effective operational relationships with his environment. The quality of the functional unity over a period of years is conditioned by the quality of the process of integration. When the individual reaches a high level of integration there is an absence of internal conflicts and a tendency to solve his problems by emotional impulse. The quality in the process comes through purposeful, social, deliberative, intelligent action. Such quality promotes functional unity by aiding each individual to upbuild the logic of his experience. This improvement in organization of experience must be accomplished by each individual for himself. No other person can do it for him. Thus integration is a qualitative growth functioning of each individual.

Under this conception there are integrated personalities, but there are no integrated curriculums. All experiences tend to further or

to retard integration. They are never neutral. Personality usually refers to the way in which an individual approaches and resolves his everyday problems of living. Integrating relates to the quality of such approach. The behavior of a person with an integrating personality is based upon study, inquiry, appraisal, anticipation, and acceptance of consequences of action before and after the occurrence, all of which are unified through confidence in his ability to reach reasonable ways out of his dilemmas. Such a personality is dynamic and unique. It is not traditional and conventional. It is a powerful force for stability and security when an individual faces the novel yet critical aspects of experiences. And every curriculum by whatever name it may be called either promotes or hinders such personality development.

There is in practice a type of curriculum called the integrated curriculum or integrated program. It represents a number of subjects or activities or experiences selected, organized, and unified by adults within a framework defining the overall pattern to be achieved by pupils. Advocates argue that such a unified organization of what adults expect children to learn better aids children to improve the process of their own integration than when adults organize such learnings more loosely as in the traditional subject curriculum. Critics point out that the real curriculum is composed of those learnings which each individual accepts to act with, through, and on in each new experience. These frequently have little relationship to the learnings set out beforehand by adults. Since integration is a qualitative process, adults can aid children better by finding out what problems children are trying to solve and helping them to improve the process toward increasingly intelligent action. Thus adults might easily increase the percentage of integrating personalities among children as well as among themselves.

What has been said about the integrated curriculum and program also explains such terms as integrated subject matter or integrated studies. Both refer to some new unification of smaller parts of a larger program sometimes within a single subject such as history or among subjects such as history, English, and art.

INTELLIGENCE. Definitions of intelligence range all the way from the broad, inclusive description of intelligence as the ability to make adaptations to a changing environment to the more specific description of intelligence by Spearman as the eduction of relations and the eduction of correlates. From the content of mental tests for measuring intelligence one would infer, in the case of verbal tests, that intelligence is the ability to score on tests of vocabulary, range of general information and perception, and use of relations; in the case of non-verbal tests, one would infer that intelligence is the ability to fit blocks into holes, to complete pictures or to find what is wrong with defective pictures; in the case of aptitude tests, one would infer that intelligence has to do with quickness of manipulation, fineness of discrimination, and ease of acquiring simple skills. All intelligence tests involve the determination of levels of attainment or levels of performance. These are usually expressed in terms of age norms, that is, in terms of the levels of attainment or performance of the mid children of successive chronological age groups.

To explain the increase in scores from age to age which occurs on every type of intelligence test, intelligence is frequently interpreted as a process of maturation which takes place rapidly in the early stages, slows up at later ages, and eventually ceases. The use of such an index as the *intelligence quotient*, with its assumed constancy, implies that intelligence is some quality or characteristic of an individual which is independent of his level of attainment or performance, a rate of maturation which varies from child to child but which slows up for all children as they grow older and which reaches its limit at younger ages for the less gifted than for the more gifted children.

These views regarding the nature of intelligence are conflicting and confusing as well as lacking in definiteness and precision. Spearman's descriptive definition of intelligence as the ability to see and make use of ideas or relationships of similarity, time, place, quantity, cause and effect, etc., be-

INTELLIGENCE

tween or among sensory feelings, abstract qualities, or more and more complex ideas or relationships themselves, may be far more adequate even though limiting intelligence to a much narrower range, than the definition of intelligence as the making of adjustments to a changing environment through the perception and use of ideas.

Such fixed reactions as reflexes, instinctive responses, or habits, whether inherited or acquired patterns of motor response, are excluded from most discussions of intelligence. With changes in the environment—changes in either the physical aspects or the meaningful aspects—new responses are evoked. These may come as a result of a trial and error or trial and selective procedure, as in the forming of a simple or more complex skill; or may result from the quick seeing of what to do, as in solving a simple problem in arithmetic; or may be achieved through a longer process of abstraction, as in seeing how an algebraic process works through the solving of many exercises involving the process in varying degrees of complexity; or in creatively evolving a means of attaining some remote end, or a theory to be tried out experimentally in science. These are all recognized processes of learning, involving the use of intelligence. Even in the acquisition of a skill, what is being done at any successful change in performance may be seen intellectually and applied in further or more rapidly perfecting the performance. When we compare children of the same mental age, but of different chronological ages and therefore of different degrees of brightness, we find that they are very much alike in the kinds of ideas they have already learned, although the dull children took a much longer time to acquire these ideas than did the bright. When we present them with new things to learn, the children in the less gifted group have fewer ideas with which to analyze a situation or work out a solution to a difficulty. They need many more exposures to analyze a situation even though they have as adequate a background of information as a brighter, younger child. They also have more difficulties in the trial and selective process of thinking that is needed for the solution of some problems. To make an intelligent criticism of a tentative solution they need a wider basis of fact to reach as adequate an evaluation as the brighter

child, but unfortunately they tend to take less into account when making their judgments. The children in the less gifted group require more trials in perfecting a skill, more exercises to see how an algebraic process works, more exposures to reading situations to make the same amount of improvement in reading comprehension. These differences in rates of learning—in acquiring skills, in seeing new and more complex ideas, and in perceiving the uses of ideas—are commonly considered differences in intelligence.

In the same individual there may be differences in the rates of learning of different skills, such as skating and penmanship; or in the rates of learning different kind of ideas, such as those found in literature and those found in mathematics; or in rates of acquiring different kinds of attitudes, such as racial superiority and tolerance. There are, nevertheless, relations among these rates of learning that suggest a general rate of learning in related functions.

Conditions other than rate of learning are also involved in the attainment of higher levels in any function. While the background of ideas is an integral part of mental ability to meet new situations successfully, it is not considered an integral part of native intelligence, even though the kind and number of these ideas greatly influence the functioning of intelligence. For the acquisition of the more complex ideas in any subject the possession of an adequate sampling of simpler related ideas seems as essential as the mastery of the simpler reactions is necessary to the acquisition of a higher level of performance in a skill. These backgrounds of simpler skills and ideas may make it feasible for the more complex skills and ideas to be acquired with equal ease as were the simpler ones. The more intricate and involved ideas in the last part of algebra seem no more difficult of comprehension to the student who has clearly understood the simpler processes in the first part of algebra than were there simpler processes at the time of their acquisition. There is even a very direct relation between the proportion of complex ideas and the proportion of simple ideas that have been learned up to any level of attainment in the case of either the gifted individual or the dull individual.

There are still other conditions that influence the functioning of intelligence, such as

the number of ideas that may be held in mind at one time or the capacity to see small differences in processes or in qualities. These abilities seem more closely a part of native intelligence than the background of ideas. But the levels of these, too, are the result in part at least of the effect of familiarity with the content. The grasping of ideas which have been expressed in language and the retention of such ideas not only show intelligence at work, but also influence the functioning of intelligence.

We frequently speak of maturation in connection with intelligence as if intelligence were something like physical growth that takes place rapidly for a time, then slows up, and finally ceases altogether. This notion regarding intelligence probably came in part from our tendency to reason by analogy and in part from the fact that people become pretty well adjusted to their familiar social environment early and tend to center their learning on specialized activities soon after adolescence, or in some cases are no longer stimulated to learn at all by their social environment. The hypothesis that intelligence stops maturing even earlier than the body stops growing in height is thus due partly to the nature of intelligence tests and partly to an inadequately stimulating environment. As the more gifted children become older their attention becomes centered upon learning in some highly specialized fields which cannot be adequately sampled by the items of a general mental test. The children of average mental ability feel neither a social compulsion nor an inner urge to keep on learning in the face of their much slower progress than that of the gifted children with whom they have been compelled to compete in school and in the face of a feeling of artificiality about much that has been learned in school that has not been meaningful to them. In the case of the dull children, their drives are inadequate to overcome the monotony and drudgery growing out of the greater amount of time that must be spent by them in learning the same ideas that can be so readily learned and so much more adequately retained and used by the more gifted children. Were equally stimulating conditions for learning instituted and were the amounts learned in the specialized activities also included in the measurements, we should probably find that the same general ease of learn-

ing is maintained by the same person well on toward forty or older, and that the limit for the acquisition or modification of ideas in the case of any individual in any specialized field is fixed mainly by his normal rates of learning in that field, the amount of time devoted to learning, and the age at which serious deterioration of the cortex sets in. Changes in the structure or chemical composition of the neurones may occur at any time and may result in changes in rates of learning. However, the decreases in the amounts learned at higher ages so readily noticeable in many people are probably the result of such conditions as lack of time for learning, loss of interest, or lack of stimulation. It has become clear that the learning of certain things cannot be accomplished until either the nervous system has reached a certain age of development or until a certain background of learned reactions, simple skills, or simple ideas has been built up. Maturation in the sense of neurological development is a condition to learning. It is related to the functioning of intelligence, and also closely related to it in rate, occurring earlier in the case of individuals with the more rapid rates of later learning.

While psychologists recognize different rates of learning for different individuals and different rates of learning different kinds of skills and different kinds of ideas for the same individual, they are far from agreed regarding the bases of these differences. Though the majority are at present in substantial agreement that intelligence is fundamentally a native trait based upon heredity, they are not in agreement upon what is inherited nor upon what is the basis of intelligence. To Thorndike (*q.v.*), intelligence is based upon a large number of very specialized, independent factors, certain combinations of which may be the bases of such functions as vocabulary, spelling ability, or range of information in science. By other psychologists intelligence is considered as based on a limited number of primary abilities, each of which is relatively independent of the others. Spearman, on the other hand, has held that intelligence is based on a general factor—perhaps an amount of intellectual energy—plus several more specific factors, such as might be involved in the structure of the various sense organs and the parts of the cortex directly connected with them.

INTELLIGENCE

The amount of intelligence of an individual would depend upon the number, the combination, or the qualities of these inherited factors.

In dealing with degree of abilities, such as the ability to comprehend what is read or to spell correctly, there is the part due to maturation or the organic development of the nervous system that is essential for learning, the part due to the immediate condition of the nervous system, the part due to the effect of drives in keeping the individual attentive to ideas and persevering in the practice of a skill, the part due to the effect of the environment in presenting learning situations, and the part due to the effect of the background of acquired skills and ideas represented in transfer of learnings. The cumulative effect of all these factors over a period of years represents what is indicated by the intelligence test score when expressed in terms of mental age.

It is seen, therefore, that since the quality of functioning intelligence (and intelligence can be observed only as it functions) is necessarily due both to the environment and to the organism as it was at birth, controversy can arise as to how fixed a characteristic the quality of intelligence is. Those that uphold the theory of intelligence as a fundamentally innate quality insist that individuals who show changes of brightness or dullness have not actually changed in intelligence. What has happened is that the environment has become either more or less favorable for the showing off of that intelligence. This concept of innate intelligence can be compared with the concept of the sharpness of a knife blade. It is of a certain degree of fineness but seems more or less fine as the conditions of cutting change. However, while it is taken for granted that the fineness of the blade can be actually and permanently changed, many psychologists deny that a similar real change in intelligence can also take place.

Intelligence Tests. Intelligence tests were first developed to meet the very practical need of selecting the children who would be unlikely to succeed in school work. The main uses of the individual mental examination are still found in the selection of children of low mental ability for segregation in institutions or for special classes in the public schools or in confirming the desirability of

retaining backward pupils in the same grade in school for another year. However, increasing use is being made of tests for the selection of very bright pupils for special education. Group tests are used mainly for ability grouping.

The first individual mental examination was constructed by the French psychologist, Alfred Binet, at the beginning of the present century. When originally published (1904) it consisted of a series of tasks graduated into age levels on the basis of the production of children at each age level who were able to do them.

In the United States the development of the individual mental examination was carried forward by two American psychologists working independently: Dr. Lewis M. Terman (*q.v.*), who published the "Stanford Revision and Extension of the Binet-Simon Intelligence Scale" in 1916, and Dr. F. Kuhlmann, who published "A Revision of the Binet-Simon System for Measuring the Intelligence of Children" in 1912 and "A Further Revision and Extension of the Binet-Simon Scale" in 1922. In both of these individual mental examinations, the tasks were arranged in age levels on practically the same basis as that used by Binet except that larger numbers of cases and more refined statistical techniques were used in the location of the tasks. The mental age was likewise determined in the same manner although the technique of determining it was improved. In addition to a wider and more careful selection of tasks the suggestion of Stern that the ratio of the mental age divided by the chronological age be used as an index of intelligence—the intelligence quotient (*q.v.*)—was adopted by both Kuhlmann and Terman. In 1937 a revision and refinement of the earlier Stanford Revision was published by Terman and Merrill under the title of the "New Revised Stanford-Binet Tests of Intelligence," while in 1939 Kuhlmann published his "Tests of Mental Development," a revision and extension of his 1922 revision of the Binet-Simon Scale, based on two basic principles of Binet but containing none of the original Binet tests. In the "Tests of Mental Development" Dr. Kuhlmann introduced a new index of intelligence, the *per cent of average*, based upon a refinement of the Heinis growth curve.

Another development quite different from

those based on Binet's work is seen in the *Minnesota Pre-School Scales* for younger children. In these scales, one a verbal scale and the other a non-verbal scale, the tasks are arranged in a series of equal steps based on the assumption of a normal distribution of the functions measured in successive age groups. In these scales the measure indicates the level of difficulty at which one-half of the tasks attempted can be done correctly. This measure, which resembles the number of inches of height on a yard stick, is convertible into an age level for interpretative purposes. In place of the intelligence quotient, an index indicating the pupil's placement among children of his own chronological age is used.

In the individual verbal tests, the child may be asked to name familiar objects, to point out a named picture, to compare weights, to find missing parts in pictures, to describe pictures, to state in what way two things are alike, to repeat digits, to repeat digits backwards, to arrange jumbled words into sentences, to solve certain problems, to define given words, and to say as many words as come to mind within one minute. For very young children and for children that have language disabilities or speak a foreign language, *performance tests* are usually used in place of a verbal intelligence test. The Minnesota Scale mentioned previously contains a performance test and the Merrill-Palmer Scale, also for preschool use, contains both verbal and performance items. Probably the best-known performance test of intelligence is the Pintner Patterson which consists of a series of graded form boards into which the child must fit the corresponding sets of forms. Other performance tests ask the child to fit a nest of cubes together, to build a block tower, to trace mazes, to complete pictures, to assemble parts into an object, etc.

Most of the responses to items on individual mental tests are scored for quality, rather than being scored merely right or wrong. On form-board tests, for example, the child receives some credit if he lays the part across the hole in which it belongs rather than fitting it into the hole. Quality is judged in terms of the age level for which the task is set. The various individual tests of intelligence do not correlate perfectly with each other. Between some verbal tests and

some performance tests the correlations are as low as $+0.30$.

Tests for very young children often include items for which the child is watched rather than tested, items related mainly to motor and manual development and coordination, e.g., can walk along, can walk downstairs alone, can grasp small pellet, etc. When the whole test consists of such items it is called a *developmental scale*, rather than a test of intelligence. Age norms are developed for such scales usually in terms of the average age at which children can perform these behaviors.

As the individual mental examination takes from half an hour to two hours to administer and can be given adequately only by a skilled clinician, there developed among school people a demand for an instrument that would be less costly to use. In response to this demand the *Otis Group Intelligence Scale* was developed at Stanford University. Shortly afterwards the *Army Alpha Test* for use with adults was developed by a committee of psychologists for use in the army. These were followed a few years later by other group tests of intelligence such as the *Terman Group Test of Mental Ability*. In these groups tests of intelligence the items were almost entirely verbal ones, involving an understanding and reading ability of language. Each test consisted of several groups of different kinds of tasks with the tasks in each group arranged in order of difficulty, with specific directions for administration and specific time limits for each test. The score consisted of the number of items correctly done on all the groups of tasks regardless of their differences in kind. On the basis of median scores for consecutive chronological age groups these total scores could be converted into mental ages, and the intelligence quotient found just as in the case of the individual mental examinations.

The vast majority of group tests are verbal though a few are not. Even in the latter cases, however, the directions in most instances must be given in words. Items on verbal group tests ask the subjects to add numbers to a group which have been arranged in a certain type of series, to complete analogies, to distinguish between opposite and synonymous pairs of words, to do arithmetic examples, to complete sentences with one of a set of given words, to choose

INTELLIGENCE QUOTIENT

the best answer for items of general information, to give common attributes of specified nouns, to classify by crossing out the word which doesn't belong in the given group, to mark true or false sentences in which words have been jumbled, to follow oral or written directions in the placing of crosses in certain specified symbols or parts of symbols, etc.

A later development in the group tests involves the use of the techniques evolved in the development of the educational scales for measuring attainment in the various phases of school work. In these tests the items are not only arranged in order of difficulty in the sub-tests but they are evenly spaced in difficulty on the basis of the proportions of a normally selected group of children of the same age or grade who give correct answers. The child's score on the test indicates the level of difficulty at which one-half of the items attempted are known. These measures can be determined for each function or kind of items or for the test as a whole, and can readily be interpreted in terms of age norms where this is desirable. Not only can intelligence quotients be obtained from these tests but indices indicating the child's placement within his own chronological age group in terms of a measure of variability can also be determined for each of the separate tests as well as for the test as a whole.

Very few of the group mental tests used in schools, however, have advanced in technique of construction beyond the Army Alpha Tests except in ease of administration, ease in scoring, or more adequate selection of content. In most of them the score is still the total number of items correctly done converted into an age level. In very few of the group tests do the scores have the definite, consistent meaning of the level at which the answers to half of the tasks attempted are known, as in the case of the individual mental examinations. The main advances during the last two decades have been in techniques of construction and in the selection of content for the purpose of predicting success in some specialized function, as in the *Seashore Tests of Musical Talent*.

The intelligence test has found its greatest use in selecting the less able pupils for special treatment. It is used, too, for selecting the more capable pupils for more ex-

tended educational opportunities as in the case of the college group. It is also used in connection with achievement tests to discover the quality of work that pupils are doing in school; whether they are reaching only about average attainment for pupils of their mental level, higher than average attainment, or lower than average attainment. (See ACCOMPLISHMENT QUOTIENT, CLASSIFICATION OF STUDENTS, INTELLIGENCE QUOTIENT.)

INTELLIGENCE QUOTIENT. There are two common measures for expressing the quality of intelligence that any individual possesses, the mental age (M.A.) and the intelligence quotient (I.Q.). The mental age is an expression of the stage of mental maturity that the individual has reached, without regard to how long it has taken him to reach it. The intelligence quotient expresses the rate at which the individual is developing mentally as compared with the average rate of the population. A child's mental age is found by giving him an intelligence test and stating his score in terms of the average chronological age of large groups of children who have taken the test and made the same score. A child's intelligence quotient is found by obtaining the ratio of his mental age (M.A.) to his chronological age (C.A.). If

INTELLIGENCE QUOTIENT

the M.A. and the C.A. are the same, then the ratio, or I.Q., is 100 and the child is considered to have average intelligence.

Theoretically, this means that he grows "one mental year" for every calendar year that he lives until he stops growing intellectually. If the child has an I.Q. of 130 he theoretically grows 130 per cent of a mental year every calendar year, thus continually widening the distance between his M.A. and his C.A., with M.A. in the lead until he stops growing mentally. The child with an I.Q. of 60 also keeps widening the distance between his M.A. and C.A., but the difference is in the opposite direction since he gains only 60 per cent of a mental year for every calendar year that he lives. Thus it is seen that if the I.Q. were absolutely fixed, that is if it did not change from year to year (and if the child scored exactly the same M.A. on intelligence tests which he took not more than a few days apart, a statement which is not true), and if we knew at exactly what age intelligence stops growing (which we do not; the age is at present set variously from 16-22 and seems to differ for different individuals), then we could predict exactly a person's mental ability during adulthood.

Some of the factors which make for change in the I.Q. are test factors. As was indicated above, children do not score at the same mental age on different intelligence tests. This is notoriously true of group tests, but it is also true of individual mental examinations administered by a skilled clinician. When the tests are of radically different type, for example verbal tests and performance tests, the difference in mental age obtained by the same child on the same day may be considerable. Naturally, then, when a child is tested several times, a year or more apart, there is no reason to expect his I.Q. to remain constant if different intelligence tests are used. This is one argument that has been used to discount the changes in the I.Q. which some psychologists have found when children were placed in a different environment from that which they had experienced when first tested. However, the counter argument is brought forward that when the changes in I.Q. are consistently gains, rather than being divided equally into gains and losses, then the test factor cannot be the only factor operating to bring about the changes. These arguments and counter arguments are at present directed

mainly at the conclusions drawn by Stoddard and Wellman from studies of pre-school children. Another argument used is that intelligence tests given to children below the age of six are not reliable. The same counter argument holds here, namely that test unreliability cannot result in consistent gains in I.Q.

Consistent changes in I.Q. at higher age levels have also been found, and they have been in the direction expected from the hypothesis that a favorable environment tends to raise the I.Q., an unfavorable one to depress it. Though as many studies can be brought forward which fail to show consistent changes, it is important to note that in all studies changes in I.Q. (even with the same test used, e.g., Stanford-Binet) have been found. Theoretically, these changes have been most often interpreted as being due to test unreliability. It is expected that children will vary from year to year within 10 I.Q. points in either direction. When, however, the same child keeps varying in the same direction year after year, or groups of children describable by some common factor of education or environment show a group variation decidedly in one direction, then the argument that the changes in I.Q. are due solely to test unreliability can be challenged.

Those psychologists who uphold the theory of intelligence as a fundamentally innate quality insist that individuals who show changes of brightness or dullness have not actually changed in intelligence. What has happened is that the environment has become more or less favorable for the showing off of that intelligence. This concept of innate intelligence can be compared with the concept of the sharpness of a knife blade. It is of a certain degree of fineness but seems more or less fine as the conditions of cutting change. However, while it is taken for granted that the fineness of the blade can be actually and permanently changed, many psychologists deny that a similar real change in intelligence can also take place.

Psychologists who do not premise fixity of quality as one of the essential characteristics of intelligence claim that it is impossible to understand what is meant by a quality that is seen to change and yet is considered as non-changeable. They argue that if a child over a period of time improves his in-

INTELLIGENCE QUOTIENT

telligence score, then it makes no sense to say that he was that bright in the first place only "it didn't show up." If intelligence tests measure intelligence, then changes in intelligence quotients mean changes in the quality of intelligence.

Though these two camps are decidedly far from agreement at present, the fact that the question of fixity of intelligence is put in terms of the constancy of the I.Q. means that the hypothesis of change can be scientifically explored. What is needed is the repeated measurement of the intelligence of many children over a period of years, using comparable tests. Moreover, the children should not all remain in the same environment throughout these years. What must be determined is how constant the I.Q. is when the child is left essentially in the same environment, and how constant it is when the child has been removed to a radically different environment. It should be noticed that the question is not put in terms of whether there are differences in intelligence at birth. That children are not born alike in all characteristics is taken for granted. That the child at birth already has some characteristics which are related to the quality of intelligence which he will soon display is also understood. The current disagreement among psychologists is in terms of the rate of development. Since intelligence grows or matures, it is the constancy of the rate of growth that now forms the subject of controversy.

Data found to date can be summarized by saying that of children who have been tested several times, a large number have shown changes of a size to be expected because of test unreliability but, when this is taken into consideration, have not changed their rate of mental growth (I.Q.) substantially. Other children, however, have made and maintained substantial gains, while others still have shown substantial, even progressive, losses. A substantial change does not mean a change from genius to dullness, or the other way round. So few studies have tested the same children at least three times in succession that there is little data to indicate how many individuals maintain their gains or losses. Furthermore, when changes are reported as group gains or losses one cannot determine how many individual children showed fluctuations in I.Q. Studies which do report the

percentage of subjects who showed I.Q. changes of specified amounts have been studies of two testings only, so that there is no way of determining what the fluctuations would have been on a third testing. While it is impossible, when there have been only two testings, to tell whether an individual child's change in I.Q. is a real change or is due solely to the inaccuracy of the tests, it is important to note that such changes are sufficiently common and sufficiently large to question the practice of describing a child's intelligence from the results of a single test. In one study after another, involving thousands of children, approximately 50 per cent of the children are found to vary more than five I.Q. points on the retest from what they scored on the first test, while about 20 per cent vary 10 or more points in I.Q.

Taking various investigations which have attempted to study the effect of different environmental variables on I.Q., and reporting the results obtained by the authors in terms of their own analyses of their data, we may summarize the findings as follows:

1. Prior to the age of 6 there is much more fluctuation in I.Q. than after that age.

2. Children in certain nursery schools showed a group gain in I.Q. after attendance at the school, children in other nursery schools did not show such a group gain. In all the schools some of the children lost I.Q. points while others gained. The reputations of the nursery schools which did and did not show gains were often equally good.

3. Studies of gifted children show that the vast majority of them maintain their high I.Q. status. A number of investigators have found that bright children increase their I.Q.'s at successive testings.

4. Feeble-minded children generally show a decrease in I.Q. with age. In certain cases where a special environment and education was provided, very little decrease was in evidence. Some investigators report that under certain "enriching" conditions feeble-minded children have shown gains in I.Q.; others report that enriching conditions have had no such effect.

5. Of four elementary schools, all rated of high quality, and in all of which the pupils were above average in intelligence, two showed no reliable group gain in I.Q. after several years of attendance, two schools did show a reliable gain.

6. Many studies which try to investigate the effect of environment on I.Q. do not do so by successive testing of the same children. Rather they compare the I.Q.'s of children who have been exposed to the same environment for different periods of time. Thus, the I.Q.'s of children living in impoverished environments, such as canal boats or river boats, are compared with the I.Q.'s of their older siblings; the I.Q.'s of children confined for the most part to the four walls of an institution, such as certain orphanages, are averaged separately for those who have lived in the institution for different numbers of years. In the majority of these cases, the mean I.Q.'s progressively decrease as the groups have lived longer in the meagre environment.

Even from the short summary given here, it is seen that it is impossible, at present, to decide conclusively to what degree I.Q. fluctuations are due to test unreliability and to what extent real changes occur. The evidence so far does point to the conclusion that very large changes in I.Q. are not to be expected. Whether real changes from 5 to 15 I.Q. points can be deliberately brought about and maintained seems at present to be very much of an open question. Those who already answer the question in the affirmative add that the time when such change is most easily brought about is in the early years. Those who are equally convinced that the answer is negative mainly discount the possibility of adequate measurement of intelligence during these early years and therefore maintain that it is impossible to know whether intelligence is being improved during this time. All investigators agree that the controversy cannot be resolved unless large numbers of children of varying I.Q.'s are brought up in a psychologically rich environment and tested at regular intervals over a period of years. INTERACTIONISM. There are two senses in which this term is employed in education. The older one stated the psychological or philosophical theory that, in spite of the difficulties involved in the dualism, an immaterial mind could affect and be affected by—interact with—a material body. The newer one states the theory that education is not so much a reaction of the child to his environment as an *interaction* between the two. Thus a habit may be said to belong as much to the stimulating environment as to the child.

INTER-AMERICAN UNIVERSITY OF THE AIR—See RADIO IN EDUCATION.

INTER-CLASS VISITATION. *Inter-class visitation* usually refers to the practice of one teacher's visiting another teacher's class as a means of improving the quality of teaching of both. The stimulus of having a colleague watch the conduct of one's class is counted as very important in leading a teacher to put forth his best efforts and to keep up with the best practices in his field. Likewise, the stimulus that comes to the visiting teacher from seeing how a colleague carries on work in a related or somewhat different field is thought to be of considerable value. Perhaps the most important outcome of all is the opportunity for both teachers to discuss critically their common problems and to help each other in areas in which one may be strong and the other weak. Much of the success of such a plan depends upon the informal spirit of friendly cooperation and mutual respect that a school is able to instill among its faculty members. Failing such an atmosphere, the practices of inter-class visitation may fall into the ruts of formality, indifference, or suspicious hostility. Much can be achieved if teachers, with the help of capable supervisors, are planning the work and the curriculum of the school together and are even teaching some classes jointly. R.F.B.

INTEREST, MANY-SIDED—INTERSCHOLASTIC COMPETITION

INTEREST, MANY-SIDED. It is Herbart's merit to have used the concept of interest, well known to the educators before him, as a basic issue for systematic educational research and practice. Interest—he says—in order to motivate the child sufficiently for learning and personal development, needs depth (*Vertiefung*) and many-sidedness (*Vielseitigkeit*). Uncoordinated and flighty interests lead only to instability and self-indulgence, whereas merely one-sided interest would render a person narrow and illiberal. The demand of both many-sidedness and depth of interest leads Herbart to ask on the one hand for a systematic, coherent and broad curriculum, and on the other hand for the refusal of all merely encyclopedic learning. (See HERBART.) R.U.

INTERNATIONAL SCHOLARSHIPS AND FELLOWSHIPS—See SCHOLARSHIPS AND FELLOWSHIPS, INTERNATIONAL.

INTERNESHIP PLAN OF TEACHER EDUCATION. An interne teacher is usually regarded as one who has completed the formal requirements for teaching and who is engaged in the first year of actual teaching. The aim of interneship is to give practical experience on the job in a way that will provide for the new teacher a gradual transition into the responsibilities of full-time teaching. Interneship also gives the young teacher supervisory help when it is most needed, allows considerable time for further professional growth before the interne becomes a full-fledged teacher, and provides a period of probation and evaluation of his work.

An interne often does not carry a full-time teaching load, and thus receives that proportion of a regular salary which corresponds to the length of time he teaches. He may or may not continue college work during his interneship, depending on the plan under which he operates. In general, the interne receives spe-

cial supervision during the year either from the college or institution where he received his preparation, or from the school system in which he is engaged, or from both in cooperation. To be most successful, an interneship plan usually requires planned cooperation between a school or school system and the institution of teacher education. (See TEACHER EDUCATION.) R.F.B.

INTERSCHOLASTIC ATHLETICS—See ATHLETICS; INTERSCHOLASTIC COMPETITION.

INTERSCHOLASTIC COMPETITION. Interscholastic competition exists in both curricular and extracurricular activities in secondary schools; in colleges, almost entirely in extra-curricular activities. In some states state-wide contests are held for high school students in the form of written examinations in most curriculum subjects. Music contests, especially, are prevalent for individual student musicians, bands, orchestras, and choruses. Some states have music-recognition contests for which students are taught to recognize any part of one hundred or more compositions. Among extra-curricular activities the chief competitions are forensic and athletic. (See ATHLETICS; DEBATING.) State-wide high school debating leagues and eliminations, as well as declamation contests, are common. The individual contests among colleges may be interstate. Some debating teams travel the length and breadth of the nation to meet opponents. Such activities are promoted not only by colleges themselves but by national forensic fraternities like Delta Sigma Rho and Phi Kappa Delta, the American Legion with its national Constitution contests, and regional organizations in all parts of the country. Athletic competition gets still more prominence. Football, basket ball, and track are especially popular, though teams compete in most other sports as well.

It is difficult to appraise interscholastic competition, for its results are various and far-reaching. It stimulates interest, self-discipline, and high-quality performance, not least in many institutions and communities where the activities might otherwise not exist. It promotes communication among institutions and students, with an accompanying breadth of experience and sense of national unity.

Football in particular has also brought money for the development of other sports. On the other hand, many educators wish to lessen interscholastic competition and to encourage intramural activities. This trend has apparently arisen because interscholastic competition has been open to only a small percentage of students; because it tends to become commercialized; and because the great publicity, attendance, and accompanying social events distract attention from the primary purpose of educational institutions. (See EXTRACURRICULAR ACTIVITIES.) M.G.F.

INTERVIEW. The interview is used in a variety of ways in education. As an informal device in the hands of the teacher it is used to inquire into pupils' learning difficulties, interests, attitudes, background, etc. It is employed also in conferences between teachers and parents. The counseling interview and the social or psychiatric case interview, although giving an appearance of spontaneity, are likely to be carefully planned, and conducted according to principles that have been developed by trained workers.

The interview has been widely utilized in the selection of teachers. In the case of competitive examinations, as are held by boards of examiners in certain cities, the interview is conducted as part of the examination to ascertain fitness in areas not covered by other means, such as a written examination.

The research interview is employed as a method of securing the judgment of experts as well as a device for gathering information. Because of the complexity of educational problems and the diversity of circumstances under which educational agencies function, it is rarely possible to achieve adequate knowledge of a significant educational phenomenon without consulting the experience or information of persons in the field. The interview, when properly executed, may be an effective and indispensable instrument of research.

Although each interview must be conceived and conducted according to its peculiar purpose and the circumstances surrounding it, several suggestions are generally applicable. First, rapport and cooperation must be assured; that is, the interviewer must develop the type of relationship with the person being interviewed that encourages that person

to speak freely because he is convinced that the interviewer is sympathetic and understanding. Second, a well planned schedule of questions or matter to be covered must be prepared in advance of the interview. Third, the questions and the approach used must be modified during the interview to meet varying conditions. Fourth, the interview must stimulate but not suggest responses lest the interviewer be led astray by too cooperative subjects who wish only that the interviewer receive the kind of information he is seeking, regardless of fact. Fifth, an objective but inobtrusive method of recording data must be employed, since too obvious a procedure for recording responses may inhibit the free expression of the person being interviewed.

An extensive literature on the conduct of the several types of interview is available. (See GUIDANCE; RESEARCH, EDUCATIONAL.) H.H.A.

INTRA-MURAL ATHLETICS — See ATHLETICS.

INTRINSIC METHOD (READING)— See READING, METHODS OF TEACHING.

INTRINSIC MOTIVATION—See MOTIVATION.

INTROSPECTIVE PSYCHOLOGY — See PSYCHOLOGY, SCHOOLS OF.

INTROVERSION denotes the tendency of being subjective-minded or being preoccupied with one's own thoughts and feelings. The term is applied to both an attitude and a type of personality. The introvert tends to resort to daydreaming and imaginative processes when confronted with problems. He shies from frontal and active attack.

The *extrovert* type is the theoretical opposite of the introvert type. The extrovert is more dominant, more active in group projects, and more objective minded, while the introvert is more introspective and more inclined toward quiet seclusion. The extrovert is more

INTUITIVE GEOMETRY — INVENTORY

inclined towards sports, games, directing social and business enterprises, or exercising overt leadership roles. The introvert is more likely to be the industrious student, the author, and editor, or the person interested in the fine arts.

Jung's suggestion of introvert and extrovert types has led to much confusion and inability to arrive at any stable definition. Except in extreme cases, both the introvert and the extrovert are normal. In fact, these two types can seldom be clearly differentiated, as an individual may be more introverted at certain times than at other times, more introverted in certain activities than in other activities.

An *ambivert* is an individual whose personality has a moderate degree of the subjective withdrawing of the introvert and the objective outgoing interests of the extrovert. This characterizes the "average" individual whose attitudes are neither excessively withdrawn nor socially overdeveloped.

The teachers' attitude toward introversion in children has been changed markedly in recent years. Traditionally, teachers have ignored introversion as a source of emotional difficulty; indeed, the child who kept to himself and spent his afternoons in reading was often hailed as the model child whose behavior should be emulated by his more active classmates who were always getting into trouble by talking among themselves during school hours. Wickman, in his widely quoted study comparing the teachers' evaluation of child behavior with that of specialists in child guidance, found that teachers attached more significance to extrovert types of behavior than to such withdrawing reactions as shyness, fearfulness, and sensitiveness.

One of the results of the growing interest in mental hygiene in education has been the increased prominence given to marked introversion as both a symptom and a source of emotional maladjustment. Psychiatrists, aware of the fact that the extreme extrovert ordinarily attracts so much attention to himself that his problems are not allowed to go unnoticed, have pointed to the adjustment difficulties which are complicated by extreme introversion. Since the traditional school tended to exalt introvert behavior and to inhibit extrovert behavior, psychologists and psychiatrists have urged the wisdom of a change in the teacher's set of values. These

suggestions have been misinterpreted by some teachers who now regard all introvert behavior as undesirable and who fail to see that both introversion and extroversion are normal traits. The recommendation that teachers not ignore the emotional problems of the introvert has sometimes led to the teacher's regarding even a mild degree of introversion as a symptom of inevitable emotional breakdown.

INTUITIVE GEOMETRY—See MATHEMATICS, TEACHING OF.

INVENTORY. The *school inventory* is a complete record of all items of school property, giving the description, location, and value of each item, and serving the following purposes: (1) it makes possible the maximum use of equipment and supplies; (2) it assists in preventing unnecessary purchases; (3) it indicates items in need of repair and those needing replacement; (4) it aids in determining values and in adjusting insurance claims; (5) it provides available records for use in determining depreciation, in calculating school costs, and in making the budget; and (6) it impresses upon school officials and employees the necessity for the proper use and care of the property. The inventory is of primary importance in school property management, since efficient management requires adequate records. Principals and teachers of most school systems make annual inventories on forms provided for the purpose.

A *perpetual inventory* is a continuing up-to-date record of all property, giving descriptions, locations, and values, together with information concerning condition, disposition, and use. The perpetual inventories are usually kept in the administrative offices where they may be referred to easily. This kind of inventory should be filed in visible

record files—trays containing pockets in which large cards may be inserted. The cards, eight by nine inches, are especially ruled to provide space for a brief description, amount, location, price, and present condition of each article. The perpetual inventory, by means of withdrawal slips, shows all transactions affecting each item and gives an accurate case history for each article carried in stock.

Textbook inventories check titles, authors, publishers, condition, and number of books in storage and in use in each room, and the disposition of books not in use. The textbook inventory is especially useful in checking requisitions and in the distribution of instructional materials; it is required in states that provide free textbooks.

ITALIAN, TEACHING OF—See MODERN FOREIGN LANGUAGES, TEACHING OF.

ITALY, EDUCATION IN. Modern Italian education can be better understood against the background of the political history of the country. It was not until 1870 that Italy was unified under the leadership of the King of Piedmont. The Piedmontese statutes became laws of the new country and were substituted for the different laws of each small state. In most of these states there had not been a school system. Except for universities, education had been entrusted mostly to religious orders and to private initiative and was usually the privilege of the well to do.

In the first decades of the kingdom the aims of educators and legislators were the fight against illiteracy, the spreading of scientific and technical education, the separation from the Roman Catholic Church, and the strengthening of an educational system

inspired by the principles of social and human progress. Instruction in the elements of the duties and rights of the individual were substituted for religious education and spiritual direction. Education was expected to develop and satisfy the interests of the child toward concrete and perceptible facts, and to create in the pupil a second nature by developing fixed habits. A. Gabelli, A. Angiulli, R. Ardigò and L. Credaro, all of them connected with the positivistic philosophy, were the most representative educators of this period.

The early years of the twentieth century saw the beginning of the new Italian idealism. The new philosophy gradually pervaded the schools of education; however, school curricula and legislation were still inspired by the old trends.

The Italian school system underwent a decisive shift in policy in 1923, when Giovanni Gentile, the well known philosopher, who is considered with Benedetto Croce the representative of Italian idealism, was minister of education in the first Mussolini cabinet. This shift, which is known as the Gentile Reform, was considered as a stepping-stone in the history of Italian education. It was the aim of the new laws to reconcile in the concrete reality of the school two opposite trends, that is, the free development of the child's and teacher's personality, and the strict subordination of youth and of the school system to the national ideals and goals. According to Gentile's philosophy, education is the "spontaneous development of the pupil in relation to his cultural environment," and it requires the intimate and profound union of pupil and teacher. The process of education is not a process of teaching and learning; it is the progressive acquisition by the individual of the consciousness of his spiritual value and creative power. On the other hand the state, being "an ethical entity" and representing a moral life to be realized, "teaches and must teach." "In the school the state itself becomes real." The reconciliation of these opposite principles can be reached only through an ideology which postulates that the individual cannot attain his full reality outside of the collective life of his nation.

In fact, the tendency of education in Italy during the last twenty years has been an

ITALY, EDUCATION IN

ever-growing subordination of the educational system to Fascist ideas and to the need of the totalitarian state. The most important steps in the Fascitization of the Italian schools were the centralization of the administration, which began in 1923 and was completed step by step; the adoption of the state textbook in the elementary schools (1929), and the control of the ministry of all textbooks for secondary schools; the transfer of elementary schools from municipal administrations to state (1933); the establishment of the *Opera Nazionale Balilla* (National Youth Organization) intended to promote the physical, political, premilitary, vocational, and religious education of Italian youth (1923), and the compulsory registration of all pupils and students in the organization; the establishment of the Fascist Academy of Physical and Youth Education (1927) for the training of a specialized body of teachers, better qualified to indoctrinate the young generation; the regulations enforcing the teaching of military instruction in all schools (1935). Enforcement of religious instruction first in elementary schools (1923), and later in secondary schools (1929), after the treaties with the Holy See, has to be considered a distinctive trait of the new educational trends in opposition to the principles of the pre-fascist era. Some of the above mentioned regulations represent a further development of the Gentile Reform; others appear to be in open contrast to the basic principles of Gentile's philosophy which, however, had paved the way for this development.

The Educational Charter, issued in February 1939, with the approval of the Fascist Grand Council, synthesizes the principles which should have inspired a further and more radical codification of Fascist education, if the enforcement of the new law had not been postponed because of the war. The following quotation summarizes the ideology underlying the Charter: "In the Fascist regime the school age and political age coincide. Schools, the GIL (*Gioventù Italiana del Littorio*, i. e., Fascist Youth Organization) and the GUF (*Gruppi Universitari Fascisti*, i. e., Fascist Groups of University Students) together constitute a single instrument for Fascist education. Compulsory attendance in these makes up the scholastic service which

inspires the citizens from the earliest age to the age of 21." The implementation of the Charter was postponed on the outbreak of World War II.

The Minister of Education is the chief executive in the Italian school system. He is appointed by the King and is responsible to the Prime Minister. In his legislative and administrative rôle the Minister is assisted by various councils and commissions, and by a body of inspectors. The most important of these councils is The Higher Council of National Education, whose 54 members are appointed by royal decree on the proposal of the Minister. The secretary of the National Fascist Party is a member *ex officio* of the Council. The departments of the Ministry of Education are (1) Higher Education; (2) Classical Scientific and Normal Institutes; (3) Technical High Schools and Institutes; (4) Elementary Education; (5) Antiquities and Fine Arts; 6) Bureau for General Affairs, Personnel, and Libraries. Universities and institutes of higher education, as well as music and arts schools, are administered directly by the Minister. All other types of schools are controlled by the Ministry through the Royal Supervisor. The supervisors are assisted by a Disciplinary Council and by School Inspectors and Educational Directors, and share with them their administrative and disciplinary responsibility. The chief educational officer in every school is the Director or the Principal.

Although several provisions of the Gentile Reform were intended to favor private schools, governmental schools far outnumber private schools of all types. The greatest share of the support of the school system is borne by the government, notwithstanding the fact that a number of universities, industrial high schools, and institutes are in part supported by private and local organizations and councils.

Only elementary education is free. Fees are very low in the prevocational schools (*Scuole di Avviamento Professionale*). For all other schools there are admission, matriculation, promotion, and examination fees. Partial or total exemption from fees is granted to honor students and to children of large families. According to the law, school attendance is compulsory for children between the

ITALY, EDUCATION IN

ages of 6 and 14; however, the mechanism of enforcement is seldom utilized.

Only a limited number of kindergartens take care of part of the children of pre-school age; in the school year 1936-37 there were 9589 kindergartens in the whole country. The regular elementary course consists of five school years. Children who have satisfactorily completed the highest grade available in their community and who are not yet 14 years old are exempted from further school attendance. This means that in the great majority of the rural sections children are not expected to attend more than the third or fourth grade of elementary school. In the school year 1936-37, for which official reports representative of the close of the pre-war period are available, there were in Italy 129,580 governmental elementary schools and 7067 rural schools. Out of 5,341,125 children of school age (between 6 and 14), 4,771,453 attended public elementary schools, and 265,915 rural schools.

After completing the elementary school, children below 14 who do not register in high schools are expected to attend prevocational schools (three years) or prevocational courses (two years or one year). In the same year (1936-37) there were 616 Royal Prevocational Schools (295 of the commercial type, 226 of the industrial and artisan type, 93 of the agricultural type, and 2 of the nautical type), with a total enrollment of 167,960 children; 144 private approved prevocational schools (mostly of the industrial type) with a total enrollment of 16,928 children; and 767 Royal Prevocational Courses (mostly of the agricultural and industrial type) with a total enrollment of 39,824.

Secondary schools are classified in two groups. In the first group are (1) the classical gymnasium-lycée (8 years course: 5 years gymnasium, 3 years lycée) which is still inspired by the principles of humanistic education, offers a curriculum where classical languages, history, philosophy, and literature are the basic subjects, and which is intended to prepare for universities those who will constitute the leading class of the nation; (2) scientific-lycée, a 4 years course offered after 5 years of gymnasium, to students who will qualify only for the scientific and technical faculties in universities and schools of higher education; (3) normal in-

stitutes, a 7 years school intended for the training of elementary teachers. In the school year 1936-37 the total enrollment in the above mentioned schools was 307,460, the majority of the students attending the Gymnasium-Lycée and the Normal Institute.

Under the heading of technical education are included technical high schools and technical institutes. The great majority of technical high schools are of the industrial and artisan type, and grant a diploma of skilled worker or artisan after a three-year course. Commercial and agricultural high schools award diplomas of bookkeeper and of rural agent. Technical institutes (4 years lower course and 4 years higher course) are intended to train young people for higher clerical positions and for technical professions such as accountants, surveyors, technical and agricultural experts with various specializations, shipbuilders, etc. The total enrollment in technical schools and institutes in the same school year was 320,861. Although technical schools are controlled by the Ministry of Education, organizations representing employers and employees exert a strong influence on the policy and management of schools intended for the education of industrial workers. *Besides the full term schools, continuation schools on a limited scale are open to artisans, skilled and unskilled workers, and agricultural workers.* Schools and institutes for artistic education were entirely reorganized in 1933. They include artistic lycées and academies of fine art, various types of schools and institutes of applied and industrial art, approved musical lycées, and conservatories.

Whereas elementary schools for boys are separate from elementary schools for girls, all secondary schools are coeducational except for those of the industrial type and for a few Women's Normal Schools where home economics and sewing teachers are trained. Admission to every kind of secondary school, admission to the higher course of each school, and graduation are attainable only through uniform national examinations.

According to the Gentile Reform universities were intended to give general scientific training and were granted broad autonomy in administration and teaching. Every faculty was permitted to establish its own curriculum, provided certain requirements as to

ITALY, EDUCATION IN

number of credits and basic courses were met. Through national examination professional licenses were granted to applicants who had obtained the required degree. In recent years, however, the autonomy of the university faculties has been entirely destroyed. The control exerted by the Ministry of Education and the Fascist Party, and the requirements set for "political and moral fitness" have increasingly limited the choice of professors and instructors.

In the school year 1936-37 there were in Italy 71,944 university students, most of whom were registered in law schools, medical schools, and schools of economics and commerce.

Adult education is entirely entrusted to the OND (*Opera Nazionale Dopolavoro*; National After-Work Organization) which is controlled by the Fascist Party and is considered as a semi-official organization. The OND absorbed all private organizations that previously had carried on popular education, those intended to fight illiteracy in the rural and southern sections as well as those that were especially directed to spread technical and scientific information in the working and lower middle class. In contrast with the pre-Fascist policy, the OND puts more efforts in perpetuating popular traditions and folklore and in artistic activities, than in spreading classroom education.

Italian education is hardly comparable to

American education. The basic American educational movement had no impact on Italian schools, and Italian educators who are widely known in this country, such as M. Montessori, (*q.v.*), had little if any influence in their own country. In spite of substantial differences in organization and curricula of these two systems, some contacts were possible at the higher education level. The American Academy of Rome awarded fellowships to American art students (See SCHOLARSHIPS AND FELLOWSHIPS, INTERNATIONAL); and the Library for American Studies in Rome provided means of authoritative information on American history, literature, and culture.

It is difficult to evaluate how much World War II has influenced the Italian school system; however, the scarce information available seems to indicate increasing difficulties in carrying through the pre-war educational program.

J

JAMES, WILLIAM (1842-1910).

William James was a distinguished philosopher and psychologist and probably the most influential thinker of his day. Having obtained an M.D. degree from Harvard Medical School in 1869, James became an instructor in anatomy and physiology at Harvard College in 1872; later, from 1880 until 1907, he continued his brilliant teaching career there in the fields of psychology and philosophy. As philosopher, James became the recognized leader of the influential American movement of pragmatism (*q.v.*), he also contributed highly original and stimulating writings to the fields of ethics, religion, metaphysics, and theory of knowledge. As psychologist, despite disinclination by temperament to conduct experiments himself, James gave great impetus to the development of scientific psychology in America. Although not a professional educator, his broad interests included a serious concern with the aims and psychology of education, and he pioneered in the application of empirical psychological principles to everyday problems of the classroom.

James's view of the ultimate objective of education is stated in terms of an individualistic rather than a social goal and reflects his biological conception of mind as an instrument of adaptation. "In the last analysis," he writes, "[education] consists in the organizing of resources in the human being, of powers of conduct which shall fit him to his social and physical world." The task of the teacher thus consists "chiefly and essentially in *training the pupil to behavior*", enabling him to make an effective adjustment to his present and future environment.

The psychological principles by which James would guide this training are fully discussed in two works of great significance in the development of modern education—his monumental *Principles of Psychology* (1890) and his later, popularized *Talks to Teachers* (1899). Empirical and biological in approach, the *Principles* was an outstanding

contribution from the functional standpoint to the new science of psychology; its broad scholarship, brilliant style, and penetrating analysis of many psychological phenomena have made it one of the most influential of modern treatises on psychology in English. With less analytical technicality, the *Talks to Teachers*—which were, in their original version, lectures to teacher audiences—attempted a "concrete practical application" of empirical psychology to educational problems, and stimulated widespread interest among educators in psychology as the proper foundation of education. In addition, both works contain many specific theories that have exercised a marked influence on the development of educational thought and practice, among them James's famous views of habit, instinct, emotion, memory, and the motor consequences of ideas.

Although the advance of psychology since James's day has outmoded certain of his educational views—for example his theory of instinct as the basis of education—others have proved to be of enduring significance for the educator. Probably James's most important specific contribution to education was his criticism of the doctrine of formal discipline in the field of memory. His rejection of this theory and his early experiment on the topic led to numerous investigations that have justified his criticism and established the modern view of the transfer of training. Much current psychological thinking also supports several of James's broader educational principles—notably his view of the indispensable rôle of interest in learning, his stress on the need for activity on the part of the learner, and his related emphasis on the desirability of concrete and non-verbalistic methods of teaching. Of probably even greater contemporary significance is James's fundamental principle that a person's reactions and their consequences in a given situation will inevitably condition his future responses to it. This, as well as other teachings of James, is an im-

JANITOR — JAPAN, EDUCATION IN

portant antecedent of the stimulus-response psychology formulated by his student, Thorndike—a point of view that has had widespread influence in the contemporary educational field. B.B.M.

JAPAN, EDUCATION IN. Education in any community or in any country has two fundamental functions: first, maintaining and diffusing the community or national culture; second, modifying the old culture or even creating a new culture. The first function may degenerate to the level of pure propaganda, indifferent to the truth but loyal to pressure. In the exercise of the second function education may break too much from all the good that may have accrued throughout the years and disintegrate into a group of unmarshalled and undirected movements. These weaknesses may appear not only in the distinctly cultural institutions but in all institutions that have an educational influence. Japan, through governmental influence, has consciously exercised both of these functions. And because of the reverence in which the Emperor is held, the National government is effective in its control and direction of education.

In Japan, where the military forces have an unusual leverage on the government, the two functions of education mentioned above are very pronounced and are subject, at times, both to marked strengths and to grave weaknesses. In brief, the army and navy leaders, by virtue of their right of direct access to the Emperor without going through the cabinet and without ministerial assent, are in a strategic position to influence the thoughts and actions of the people. These two groups of leaders can even prevent the formation of a cabinet or force its resignation by withholding or withdrawing their respective ministers.

The family tradition constitutes another factor influencing education in Japan. The

family system comprises the social unit of Japan. It consists of a whole group of people related through birth and marriage. Each family group has a recognized leader who retains his position until he reaches a certain age when he retires in favor of his eldest son.

The Japanese philosophy of life thus lends itself to solidarity and adaptation. The nation, because of the relation of the individual to the state and to the family, functions as a unit.

The Japanese are nationalistic in outlook. They are proud of their growth to a world power. They have a reverence for their state and for their Emperor. They are a thrifty, hard-working people. To them any occupation is honorable. To them education has a vital relationship to their national life.

In ancient times education in Japan was simple; it was based upon the family system. Each family transmitted to its members the family vocation, the family worship, and the ancestral rites. In 1864 the practice of public lecturing began. Feudal lords established schools for their retainers' sons. The aim of education was to cultivate ideal personality and to train government officials.

The masses of the people were taught in the *Tera-Koya*, small cottages attached to the temple, the most important seats of education before the Restoration. At the time of the Restoration there were approximately 16,000 *Tera-Koya* in Japan. Thus far education was primarily for boys.

As time progressed the influence of the United States, of Germany, and of France was felt in the Japanese schools. In 1872, Japan was divided into eight Academic Districts on the order of similar divisions in France. Each district had its university, its elementary and its secondary schools as well as middle school districts. In 1890 compulsory education was legalized; foreign teachers were brought in. On the whole, three foreign countries have contributed to the present educational program in Japan. France may be said to have had the greatest influence on the lower levels of education; the United States upon the graduate schools; while the German universities had more influence on the Japanese college.

National Philosophy and Educational Philosophy. The fundamental basis of the Japanese national life is expressed in the

Japanese word *Kokutai*. This word expresses what the Japanese mean when they think of their national culture. The word means a combination of the fundamental characteristics of the state with the latter's spiritual heritage based upon them. Education, like all other phases of culture in Japan, is inseparably linked with *Kokutai*. This close integration is well illustrated in the *Imperial Rescript on Education*. This *Rescript*, formulated by Emperor Meiji and promulgated October 30, 1890, was to serve as a basis for the fundamental changes that were being made in the educational program of Japan.

The *Rescript* is as follows:

Know ye, Our subjects:

Our Imperial Ancestors have founded Our Empire on a basis broad and everlasting and have deeply and firmly implanted virtue; Our subjects ever united in loyalty and filial piety have from generation to generation illustrated the beauty thereof. This is the glory of the fundamental character of Our Empire, and herein also lies the source of Our education. Ye Our subjects, be filial to your parents, affectionate to your brothers and sisters, as husbands and wives be harmonious, as friends true; bear yourselves in modesty and moderation; extend your benevolence to all; pursue learning and cultivate arts, and thereby develop intellectual faculties and perfect moral powers; furthermore advance public good and promote common interests; always respect the Constitution and observe the laws; should emergency arise, offer yourselves courageously to the State; and thus guard and maintain the prosperity of Our Imperial Throne coeval with heaven and earth. So shall ye not only be Our good and faithful subjects, but render illustrious the best traditions of your forefathers.

The Way here set forth is indeed the teaching bequeathed by Our Imperial Ancestors, to be observed alike by Their Descendants and the subjects, infallible for all ages and true in all places. It is Our wish to lay it to heart in all reverence, in common with you, Our subjects, that we may all thus attain to the same virtue.

The 30th day of the 10th month
of the 23rd year of Meiji.

(Imperial Sign Manual. Imperial Seal).

The *Rescript* differs from the guiding principles of education in other countries. It is at the same time both a guiding principle in education and a code of morals. A copy of this *Rescript* is given to every school in the Empire. It is read in assembly each October 30, on graduation days, and on other important occasions.

Divisions of Education. Elementary education, which embraces approximately three-fourths of the student body of Japanese schools, consists of two divisions or courses

—a six-year course, and a higher elementary course, three years in length. The latter is not compulsory. Moral and religious training as well as science are emphasized in the elementary schools. Special emphasis is given to physical and health training.

Four rather extensive types of schools are found in Japan on the secondary school level. They are the middle school, the girls' high school, the technical school, and the youths' schools. The *Koto Gakko*, the upper division of which is university preparatory, constitutes a fifth division; it enrolls comparatively few students. The youths' schools predominate both in number and enrollment. They are quite flexible and enroll students not ordinarily qualified to do secondary school work.

There are 45 universities in Japan, the function of which is four-fold: imparting essential scientific knowledge that is worth while to the state; providing research in the various branches of the sciences; building individual character; fostering the formation of the national spirit. The universities together with the special colleges and the technical colleges enroll approximately 175,000 students. Considerable attention is given to teacher-training institutions.

General Statistics of Educational Institutions in Japan Proper*

Types of Schools	No.	Students	Teachers
Primary	25,840	11,567,000	261,500
Middle	559	35,200	14,200
Girls' High Schools ..	985	433,000	13,500
Normal Schools	101	30,000	2,200
Technical Schools	1,935	260,000	19,600

JESUITS, EDUCATIONAL WORK OF. The Society of Jesus, commonly known as the Jesuit Order, was founded by St. Ignatius Loyola. A charter was granted to the Society by Pope Paul III on September 27, 1540. The first intent of the founder had been to carry on missionary work in the Holy Land, a project which was soon made impracticable. Although the needs of the period suggested participation in educational activity, especially since urgent invitations were not wanting, it was with some reluctance that he entered the work with his companions. Education is today one of the chief means by which the Society furthers its ultimate aim—the salvation of souls. Jesuits labor for their own salvation and that of their neighbors by training good Christian citizens in keeping with the motto of the Society, *Omnia Ad Majorem Dei Gloriam* (All for the Greater Glory of God).

The Jesuits experienced immediate success in Europe and by 1700 the Society controlled more than 700 universities, colleges, secondary schools, normal schools, and seminaries. Some institutions cared for as many as two thousand students. Toward the end of the 18th century, just before the Society was suppressed, there were 22,589 members in 39 provinces. There were 24 Houses, 669 colleges, 61 novitiates, 176 seminaries, and 273 missions among the savages. The Jesuit schools were caring for over 200,000 students, drawn from all classes of society, who were educated free of charge. Much of the success of the program has been attributed to the superior training of the teachers and the extremely efficient organization. Von Ranke, a hostile critic, says: "It is found that young people gained more with them in six months than with other teachers in two years. Even Protestants removed their children from dis-

tant gymnasia to confide them to the care of the Jesuits."⁴

The success of the Society aroused enmity in groups which feared the influence of the Jesuits in the Church and in court circles. The devotion of the Society to the interests of the Papacy interfered with political ambitions in high places. Agitation for the suppression of the Jesuits assumed such proportions that Pope Clement XIV was compelled, "for the sake of peace," to issue the Brief of Suppression on July 21, 1773. The schools of the Society were soon closed or turned over to new masters. A few schools continued to exist in countries in which the Brief had not been published, so that by 1776 there were 145 members scattered through twelve establishments. These formed the nucleus for a new system of schools when the Society was restored throughout the world by Pope Pius VII on August 7, 1814. While there are 12,472 Priests and 8,893 Scholastics now serving (1941) in various spiritual ministries throughout the world, the Society has never fully regained in Europe the place it occupied in the educational world at the time of the Suppression.

The Jesuit system of education is based on the *Ratio Studiorum*, the result of fifteen years (1584-1599) of study, experimentation, criticism by classroom teachers and eminent professors of the Order, under the direction of a central committee. Farrell² calls it *The Jesuit Code of Liberal Education* because (1) it formulates a systematic body of educational principles and practices shaped to an educational philosophy, and (2) it singles out the liberal arts as the core of the curriculum for undergraduate training. The classics always constitute an important part of the curriculum in a Jesuit school, though other subjects are not neglected. The same is true of scholastic philosophy. The Society has always tried to compromise between the old learning and the new, but training in the classics followed by courses in scholastic philosophy, continues to be a distinguishing characteristic of Jesuit education. Religion alone holds a higher place. Any program in which these three elements are in balance, in keeping with the principles of the *Ratio*, is pre-eminently the means to promote the formation of cultured Christian men. The spiritual, the rational and the humane meet and work in harmony.

The rules in the *Ratio* governing the duties of administrative officers, professors and students are quite specific. Instructions on methodology are just as detailed. The *Ratio* is no longer binding in the colleges, and teaching methods in the Jesuit high schools in the United States have been adapted because of curricular changes. The practice in Jesuit schools today, then, is to follow the Jesuit method of teaching as much as possible and to adapt the curriculum to conform with local requirements. Nevertheless, the *Ratio* has unquestionably shaped the thinking and practices of Jesuit educators so that there is today a distinct type known as Jesuit education. It has also served to promote the distinctive efficiency, unity and method that have been so largely responsible for the success of the Jesuits as teachers.

The Society is tenaciously devoted to the ideal "that neither pains nor expense should be spared in the formation of the Jesuit master." The candidate passes through two years of novitiate training at the outset, a period devoted almost exclusively to the cultivation of the ascetical life. The following two years are spent in the Juniorate, essentially a school of classical studies. Latin, Greek, English, history, and some elective studies constitute the program. Courses in education parallel the offerings in content subjects. The candidate, or Scholastic as he is known by this time, is also obliged to do some practice teaching. The young Jesuit next follows a carefully correlated system of philosophical training in a School of Philosophy, which is usually an integral part of one of the larger Jesuit universities. The program of the first year includes survey courses in mathematics and science. The second and third years are given to courses in psychology, philosophy, the sciences and education. The bachelor's degree is conferred after the second year of philosophy. After this extensive training, two and sometimes three years are spent in teaching in one of the high schools of the Order. Then follow four years of theological study. At the end of the third year, the Jesuit is ordained a priest. The average age at ordination is 31. The period of training for teaching covers twelve years. An individual who shows unusual aptitude in a subject is quite frequently sent to a university for his final degree; that is, after completing his training in

the Order. McGucken indicates that there is a definite purpose in such an extensive training program. "In giving these long years of preparation to this task, the Society has a triple aim in view; the Jesuit is expected to be an efficient educator of youth, an able priest, and at the same time, a cultivated man of the world."⁴

The *Constitutions*, approved by Pope Julius III in 1550, outline the purpose and organization of the Society and enumerate the means whereby its spiritual ministries are to be performed. The Order is divided into Provinces and Vice-provinces, of which there are forty-five and five, respectively (1941). Each province is governed by a Provincial appointed by the General. Several provinces make up an Assistancy, of which there are eight: English, American, Slavic, Latin American, Italian, German, French, and Spanish. Each Assistancy represents a geographical section and is governed by an Assistant. The General is chosen for life and has complete authority and power in the Society. He presides over the sessions of the General Congregation, the supreme legislative and governing body. The Congregation is composed of the Provincials and two delegates from each province. The Assistants serve as aides of the General in administering the affairs of the Society. Rectors of universities and colleges and other local superiors are appointed by the General but are accountable to the Provincials.

Jesuit Fathers, members of the English Province, cared for the spiritual needs of the Catholic colonists of Maryland during the 17th and 18th centuries. Jesuits from Belgium founded the Missouri Province in 1823. The New Orleans Province was established by the French Jesuits. Italian members of the Society extended the work of the Society as far as the Pacific Coast. Germans were responsible for a foundation in Buffalo in 1870. These Jesuit pioneers from many lands soon acquired the American spirit and rendered invaluable service through their religious and educational activities. Europe no longer supplies personnel for the Society in America, since native vocations are now quite sufficient. "The roots of Jesuit education reach down deep into the very beginnings of American history. It is truly an indigenous and native growth as much as any education in the

JEWISH EDUCATION

United States can claim to be, fostered under the best tradition which the Old World could give to the New."

American Jesuits date their educational activity from the founding of Georgetown University in 1789, even though it did not receive recognition as a Jesuit college until 1806, at the time the Society was reestablished in the United States through the influence of Bishop John Carroll of Baltimore. A corporation of ex-Jesuits had established and staffed the school during the interim, 1789-1806. After the Restoration, other foundations followed rapidly; St. Louis University, 1818; Spring Hill College (Alabama), 1830; Xavier University (Cincinnati), 1831; Fordham University, 1841; Holy Cross College, 1843. Five Jesuit institutions of higher learning have passed the century mark (1943). Others have over ninety years of service to their credit. The twenty-five Jesuit colleges and universities comprise one-third of all the Catholic institutions of higher education established originally for the education of men. They also care for approximately forty per cent of the enrollment. Eighteen of the twenty largest cities in America have Jesuit college or university facilities. The same is true for nine of the ten most populous states. The territorial spread of the Jesuit effort in higher education is impressive, yet the role the Society plays in providing professional education under Catholic auspices is still more significant. Eleven of the fourteen Catholic law schools approved by the American Bar Association are Jesuit. The five class A Catholic medical schools are controlled by the Society, and two of the three schools of pharmacy. The same predominance is true in commerce, engineering, dentistry, social work, education, and graduate studies. Members of the Society have been especially prominent in America in research in astronomy and geophysics. An astronomical observatory is maintained at Georgetown, and seismological stations are operated at Georgetown, St. Louis, Fordham, John Carroll (Cleveland), and Weston (Massachusetts). Observations and recordings are exchanged with institutions and governmental agencies throughout the world.

McGucken says that by 1910 the Jesuit high school "emerged as a distinct entity, separate from the college in administration, and in-

structional staff for the most part, differing very little in curriculum from the classical course of the public high school, and yet retaining the characteristic Jesuit spirit in its objective and in its method."⁴ A network of Jesuit high schools covers the United States. Some are boarding institutions and others care for day students only; some bear the names of great universities and others honor Saints of the Society. Most of the 37 schools are located in or near populous centers and their student bodies constitute typical cross-sections of the general population. Almost eighteen thousand boys are registered in Jesuit schools of secondary grade (1942). Twelve schools have an enrollment of from 400 to 600, and ten from 700 to 1,000.

There are 2,710 Fathers and 2,352 Scholastics serving in the seven Provinces (California, Chicago, Maryland-New York, Missouri, New Orleans, New England, Oregon) which comprise the American Assistancy (1941). The American Jesuits are also responsible for thirteen schools, including ten secondary schools, two colleges, and one university, in British Honduras, China, India, Iraq, Jamaica, and the Philippines. The American Assistancy maintains almost twice as many missionaries as any other American Catholic organization. (See ROMAN CATHOLIC EDUCATION.) F.M.C.

JEWISH EDUCATION. *Jewish Education* is a program of supplementary education offered in Jewish schools and religious institutions.

The aims of such instruction fall, in the main, under three headings: (1) attaching the child devotedly to his people and to the faith of his fathers; (2) familiarizing the student with the history and culture of the Jews and with the Hebrew language and literature; and

(3) inducting the child into functioning participation in Jewish religious, communal, intellectual, and social institutions and movements.

The instruction is usually offered after school hours on week-days, or on mornings during the week-end, or both. The time devoted to it varies from a minimum of one or two hours a week to a maximum of twelve to fifteen. A small number of parochial-type schools offers a combined curriculum of both secular and Jewish subjects.

The content of instruction varies greatly among the Orthodox, Conservative, and Reform types of schools. Among Orthodox Jews, the ritual of worship is entirely in Hebrew, as is the reading of the weekly Bible portion. This leads the schools in this group to emphasize fluency in mechanical reading of Hebrew and translation of prayers and the Bible. In the modern schools, Hebrew is also taught as a living language and subjects like Jewish history, ceremonials, religion, and modern Jewish life receive some emphasis.

The Reform group worships in the vernacular; this has greatly reduced the emphasis on Hebrew in the Sunday Schools. Instead, Bible, Biblical History, Religion, and Ethics received major emphasis until recently, when Jewish history down to modern times, current events, modern Jewish problems, demography, and similar subjects were introduced.

The conservative group stands somewhere between the Reform and Orthodox groups. In their ritual, the vernacular plays a larger rôle though Hebrew still predominates, but less so than in the Orthodox schools. The various cultural subjects taught in English receive greater emphasis than in the Orthodox schools and many of the Reform textbooks have widespread use.

In some schools advanced courses in Hebraic subjects and in Rabbinic literature may be taken. Small groups of schools here and there pursue a particular bias, e.g. the substitution of Yiddish for Hebrew as the language objective, the minimization of the theological aspects of religion, or indoctrination in the goal of pioneering in Palestine, or in some political or economic school of thought.

In addition to academic instruction many modern schools within all groups offer opportunities for practical training in worship, celebration of holidays and festivals, participa-

tion in Jewish organizational work and in charitable and social service projects, and creative expression in dramatics, literature, art, and music. Many schools have an extra-curricular program for student self-government and sociability; in fact, some institutions offer this type of program exclusively, to maintain contact with the many thousands of youth who never had any Jewish education or who left school early.

Basic to the entire program of Jewish education is a character training orientation. However, it is not introduced as a subject of formal instruction, except in rare instances, but is rather made the resultant of the religious disciplines, the parental relationships and home observances, and the general religious school activities and atmosphere.

Pedagogic methods used in Jewish schools vary from the most progressive to the most archaic. The best schools in the field compare favorably with the finest of the private progressive secular schools. At the same time a small percentage of children are taught in unattractive surroundings by hopelessly incompetent teachers who do violence to every known pedagogic principle. By and large, however, the Jewish schools are comparable in their methodology with the public schools of their community.

Physical facilities and equipment, while they vary greatly, have benefited from the wave of building activity during the prosperous '20s. This is particularly true of the schools connected with congregations, although the communal schools have also benefited. The result is that a surprisingly large number of schools in tiny communities as well as in large cities are now housed in splendid, modern school buildings. The actual value of all Jewish school buildings and equipment in the U. S. is probably close to 60 million dollars, of which approximately 35 millions represents the school property of the congregations and the remaining 20 to 25, communal school property.

The annual budget of Jewish education is probably between 7 and 8 million dollars, which, expended on the education of an approximate enrollment of 250,000 children gives a per capita expenditure of \$30 to \$35 per annum. The week day schools spend about 5 millions of this sum on the education of about 150,000 children per annum. The

JEWISH EDUCATION

Reform Sunday Schools spend about \$1,250,000 on the education of about 40,000 children per annum. The remainder is spent upon another 50,000 children in parochial schools, in supplemental Sunday Schools, in folk-schools, and under private instruction or other types of schooling involving small numbers of children.

In the main the week-day schools operate by charging tuition fees. However, since about one-third of their enrollees must be admitted either free or on part-scholarships, it becomes clear why tuition fees provide only about two-thirds of their revenue, the remaining one-third coming from philanthropic and communal sources. The Sunday schools generally operate free for children of members, children of non-members being charged a nominal fee when they are not admitted entirely free of charge. The cost of Reform religious education is paid out of the congregational budgets. In the Conservative schools the Sunday program is often provided free, as in the Reform schools, while the week-day program must be paid for, as in the Orthodox schools.

Teacher-training schools in the larger cities and within all the denominational groups, strive constantly to improve the caliber of the teachers, to increase their academic background, and to heighten their professional competence. The licensing of professional Jewish teachers is spreading in the large cities.

Even the Sunday School teacher, whose work is necessarily part-time and avocational, is more and more a product of a Teachers Institute or College of Jewish Studies. The untrained volunteer is found less and less frequently. In the smaller cities where systematic teacher-training schools cannot be maintained, the Rabbis often conduct training classes for their own teachers and hold regular teachers' meetings, conferences, and demonstrations.

In general, Jewish teachers are young (30 years, average), well-educated (3 years college, average), and experienced (5 years teaching, average). There are about 2500 full-time professional teachers engaged in Jewish educational work in the U. S. who earn an average salary of about \$1500-\$1750 per annum. Principals of schools may receive about \$3000. Some directors of Jewish edu-

cation in large cities receive approximately \$5000.

There are about 4000 to 5000 Jewish Sunday school teachers in the U. S. who receive an average monthly salary of about \$12 to \$15 and a maximum of about \$30. Supervisors in the larger schools, of whom there are over 100, may earn from \$40 to \$100 per month for this part-time work. There are very few full-time directors of Sunday Schools.

Attendance statistics for Jewish education are difficult to secure. It is estimated that among the 4,750,000 Jews in the United States, there are approximately 850,000 children of school age. The actual enrollment in Jewish schools at any one time is estimated (from surveys made in various large cities) to be about 250,000 children. What percentage of the 850,000 receive some kind of Jewish education for some length of time is not known exactly, but it is estimated to be at least 50%, and possibly as high as 75%.

The Orthodox type of school, which offers many hours of instruction in Hebrew, fails to hold its pupils for any appreciable length of time. Recent surveys have shown that more than 50% of children enrolled in these schools drop out before they have completed even one year of work. Only 5% reach the fifth grade. In New York City with about 325,000 Jewish children of school age, only about 3,000 reach the high school departments of these schools. It seems clear that only a tiny fraction of the children in these Hebrew-centered schools ever attain even fair proficiency in Hebrew language and literature. This fact is doubly significant in view of the large constituency which these schools serve, namely, about 3,500,000 of the 4,750,000 Jews in the U. S. Incidentally, in these schools boys predominate in the proportion of about 3 to 1 over girls.

The Reform type of school, offering two or three hours of instruction mainly on Sunday morning, serves a small percentage of the Jews in the U. S.: about 400,000. The proportion of children of school age is much smaller than in the general Jewish population, totalling about 42,000, of whom about 35,000, or more than 80%, are enrolled in religious school at any one time. In addition to this high percentage of attendance, the average student remains in religious school approxi-

mately 6 years, and about two-thirds of all those who are confirmed go on to take post-confirmation work. In contrast with the other schools, practically 100% of children who enroll in grade 1 are still present in grade 5; 57% of them reach grade 9 and 27% reach grade 12. The proportion of boys and girls is about equal.

Adequate information about attendance in the remaining types of Jewish schools is not available.

Youth and Adult Education have not received very great emphasis or support. Only a small percentage of youth continue their Jewish studies, though many maintain contact with Jewish institutions through youth groups, club work, and recreational activities. The youth on the college campus was largely neglected until recent years when the flourishing Hillel movement began to place competent Jewish educators and leaders on so many of the larger campuses. Adult education is carried on through the medium of study circles and adult institutes, but the number of enrollees is extremely small in proportion to the total adult population. The most important medium of adult instruction remains the sermon during the religious service. Youth and adult education and pre-school religious education are the most likely areas to be developed as the field of Jewish education expands.

Professional and Higher Jewish Education is now the privilege of a very select few, but these few have the advantage of attending institutions with scholars of world renown as teachers. There are five training schools for Rabbis, two Reform, two Orthodox, and one Conservative; a Jewish Liberal Arts college; a graduate school for the training of social service workers; a graduate school for purely academic scholarly research; and a number of high-grade teachers' training schools. The hundreds of graduates of these institutions who hold positions of responsibility in educational work, social work, and in the ministry are the backbone of the structure of Jewish education in the English-speaking world.

JOB ANALYSIS. The job-analysis approach to educational problems has been employed effectively in many situations—particularly in vocational education (*q.v.*). The problem is three-fold: first, an analysis of the duties involved in a particular job; second, the determination of the knowledge, habits, and skills required for success in the pursuit of this job; and third, the development of appropriate instructional materials.

Charters and Waples have made wide use of job analysis in curriculum construction. Their approach to the determination of the objectives of teacher education was a comprehensive analysis of what teachers are called upon to do and the identification of traits that actually characterize successful teachers. A master list of some 1,000 types of activities was derived from various sources. These were classified in appropriate categories and ranked, and techniques were developed for using the evaluated activities.

In the field of vocational education, job analysis is a standard basis for curriculum construction and definite techniques have been developed for its utilization.

Five means are used in making a job analysis. These are: introspection (a person is asked to list the duties in connection with a job); interviewing (job holders list their duties and a master list is prepared); working on the job (investigator secures a job, carries on operation, and notes duties); questionnaire (inquiry blank sent to workers to be filled out); summary of literature (analysis made by reading about the job).

In using the job-analysis technique there is not only the problem of securing the items involved, but also the determining of the difficulty of each item.

The job-analysis approach to curriculum

JOURNALISM EDUCATION

has not been used extensively. The principal reason for this is the fact that by itself it does not constitute a method of curriculum development, since it may fail to give leads to the controlling purposes in a curriculum enterprise. Therefore it is necessary that the information revealed by job analyses be supplemented by materials bearing on social purposes and ideals. It is because of the failure to use such additional measures in connection with curriculum construction that many of the programs in the field of vocational education have come under rather serious criticism. As a technique in determining initial requirements, however, it has great value for the curriculum maker. (See CURRICULUM.)

JOURNALISM EDUCATION. Education for journalism, as we know it today, emerged from a welter of journalistic and educational controversy over the practicability of collegiate instruction for newspaper work. This controversy still strongly influences the content of journalism curricula. In 1903, Joseph Pulitzer offered to endow with \$2,000,000 a school of journalism at Columbia University. The proposal precipitated a public argument not only nation-wide but international. Men who published comments included Presidents C. W. Eliot of Harvard and James B. Angell of Michigan; Carl Schurz and Grover Cleveland; Samuel Bowles, Henry W. Watterson and Lincoln Steffens; Viscount James Bryce and Lord Alfred Harmsworth. Their prominence and the prominence of Mr. Pulitzer attracted attention to the issue and to the growing stature of journalism. Ultimately Mr. Pulitzer decided to bequeath the money instead of giving it immediately. He died in 1911, and the Journalism School at Columbia University opened in 1912. Meanwhile, a Missouri editor, Walter Williams, formulated a definite plan for a school of journalism using ideas expressed in the controversy by editors, educators, and

statesmen. So in 1908, four years before Mr. Pulitzer's endowed school started in New York, Dean Walter Williams began at the University of Missouri the first complete division of any university in the world to devote itself to education for journalism.

Neither the idea nor the controversy was new. In 1869, President Robert E. Lee of Washington College in Virginia appointed a Virginia editor to give practical instruction to fifty scholarship-holders in the college who "intended to make journalism their business in life." This was the first attempt to combine instruction in journalism with liberal arts courses on a collegiate level as education for newspaper work. The announcement stirred public discussion in the New York, Richmond, and Louisville press. From 1879 to 1885, a course in Political Economy at the University of Missouri included "the principles of journalism as illustrative material." Cornell began a journalism course in 1888; the University of Pennsylvania in 1893; and the University of Kansas, 1903. But no independent division for journalism education appeared between 1869 and 1908. The first journalism course offered in a European college was begun at the University of London in 1919.

Today (1943) 542 institutions offer instruction in journalism: universities and colleges, 418; teachers' colleges, 103; Negro colleges, 21. Of these, 32 institutions have accredited professional schools and departments of journalism which meet the "Class A" requirements for membership in the American Association of Schools and Departments of Journalism; 71 have schools and departments offering degrees or majors in journalism which do not meet AASDJ requirements; 55 offer substantial programs in journalism, usually as divisions of English departments having combined English and journalism majors, or journalism minors; 384 have limited journalism programs, usually carried as English programs and in most cases counted on the English major but not constituting an independent minor.

The controversy begun in 1869 and resuscitated in 1903 focused editorial and educational attention upon two opinions: that a broad discipline in history, social science, and literature was most important for journalism, and that other skills and talents in-

dispensable in newspaper work could not be learned "outside a newspaper office." Many journalists, educators, and students were skeptical. So, from the beginning to the present, education for journalism has emphasized the two dual objectives: that of stressing both liberal arts and actual newspaper office techniques in the journalism curriculum, and that of emphasizing scholarship in background courses while satisfying editors by sending them young men habituated to actual newspaper office traditions and techniques. A prime objective of journalism teaching is to show students the importance of background courses for journalism and to show them how to use a background knowledge in newspaper work.

The first statement of "requirements for a journalism degree" (in 1908) stipulated that 75 per cent of a student's work must be in nonprofessional "background courses"; that professional newspaper men who were also university graduates constitute the professional course faculty, and that the teaching of journalism courses simulate actual newspaper procedure with the publishing of an actual newspaper as the laboratory product. With minor variation, this principle has been the criterion. An analysis of degree requirements in the 32 professional schools of journalism with AASDJ membership shows that an average of 76.7 per cent of the program is devoted to background courses; only 23.3 per cent to professional courses.

The first two journalism schools (Missouri and Columbia) each taught in at least one professional course the social function and the ethical responsibility of the press. Since the early twenties, a curricular trend, accelerated in the early thirties, has added more and more professional courses which attempt to place the newspaper in its social framework. The movement has effected a social enrichment of journalism curricula. Instructors explore the field of communications, foreign newspapers, public opinion and propaganda, newspaper problems, the press as a factor in international relations, social problems in journalism, and similar study aimed at providing an education *in* journalism as well as *for* journalism. All thirty-two of the AASDJ schools have adopted curricula devoted not only to the practices of journalism but also to a social evaluation of those prac-

tices and to a scholarly understanding of public affairs in ways which can bring that understanding to a broad public through journalism. A consensus expressed by Association members for twenty years is that the study of journalism should not follow the practical blindly but should become an intellectually free pursuit of knowledge of the press, of what it has been, of what it is, and what it ought to be. Important journalism teachers unanimously agree that the aim of journalism education is two-fold: to combine scholarship with journalistic techniques so that public affairs can be made interesting and comprehensible to large numbers of people, many of whom have limited vocabularies and slight basic information, and to improve existing techniques and to study the newspaper as a social institution.

The accredited professional schools of journalism are recognized by the major newspaper organizations of the United States through the National Council on Professional Education for Journalism, representing the American Society of Newspaper Editors, the American Newspaper Publishers Association, the National Editorial Association, the Southern Newspaper Publishers Association, and the Inland Daily Press Association. The National Council occupies a relationship to schools of journalism similar to that which the Engineers' Professional Council occupies to the engineering schools or that the American Bar Association or the American Medical Association occupy toward their professional schools.

These thirty-two accredited schools report 258 faculty members. Of these, 59 per cent have advanced degrees, 63 per cent are of professorial rank. These 258 staff members show an average of 10.9 years of practical journalistic experience and an average of 11.3 years of teaching experience. The average journalism school's staff consists of 7.9 persons. All 32 schools have completely equipped news rooms and news editing laboratories; 11 have completely equipped newspaper plants; 18 have arrangements with cooperative newspapers for practical experience.

AASDJ schools are: Boston University, University of Colorado, Columbia University, University of Georgia, University of Illinois, University of Indiana, University of Iowa,

Iowa State College, University of Kansas, Kansas State College, University of Kentucky, University of Louisiana, Marquette University, University of Michigan, University of Minnesota, University of Missouri, University of Montana, University of Nebraska, New York University, Northwestern University, Ohio State University, University of Oklahoma, University of Oregon, Pennsylvania State College, Rutgers University, Stanford University, Syracuse University, University of Texas, University of Washington, Washington and Lee University, University of Wisconsin, University of Southern California.

Most journalism schools require two years of liberal arts work for admission. Only the Graduate School of Journalism of Columbia University is a strictly graduate division. Its students are selected on the basis of scholarship from applicants who hold at least a bachelor's degree. Several other journalism schools offer a master's degree, as well as a bachelor's degree, for students who continue into graduate study. A Ph.D. degree in journalism, offered for a few years at the University of Missouri, was discontinued in 1941.

JOURNEY, SCHOOL — See **TRIP, SCHOOL**.

JUNIOR COLLEGE. An educational institution which typically offers two years of education of college grade beyond the high

school level. A small number of junior colleges include also the last two high school years, making a four-year junior college. Two chief types are recognized, those publicly controlled and those privately controlled. The latter are more numerous but the former have the greater number of students.

Origin and historic background. Both types of junior colleges are products for the most part of the twentieth century. The first publicly controlled junior college now in existence was established at Joliet, Illinois, in connection with the local high school. The most significant development of publicly controlled junior colleges, however, has occurred in California following favorable constructive legislation in 1907 and frequent supplementary legislation since that time. The first California junior college was organized at Fresno in 1910. In 1942 there were 47 public junior colleges in the state, with an enrollment of regular and special students in excess of 140,000. Publicly controlled junior colleges are found in three-quarters of the states. Legislation expressly authorizing their establishment is found in more than half the states. In some states, of which California is outstanding, there is no charge for tuition; but in many, substantial fees are charged the students. California, Washington, Texas, Mississippi, and Utah are states which have made provision for substantial state support. Some publicly controlled junior colleges have grown up as extensions of local high schools. Others, usually stronger ones, have been established as separate institutions, controlled by the state, or by county or special junior college district boards.

Privately controlled junior colleges have developed in a variety of ways and it is not possible to set a definite date when junior college work, as now recognized, began in them. A few can trace their beginnings back far into the nineteenth century. Lasell Junior College in Massachusetts (then Lasell Female Seminary) was offering systematic work of college level as early as 1852. Some privately controlled junior colleges are the outgrowth of old established seminaries and academies; some have resulted from the elimination of the upper two years of small four-year liberal arts colleges, particularly those founded under denominational influence;

others have been organized *de novo* as separate institutions.

The growth of the two principal types of junior colleges during the past 25 years is shown in the following tabulations:

Year	Publicly Controlled		Privately Controlled	
	Junior Colleges	Students	Junior Colleges	Students
1917	39	1,600	93	2,400
1927	136	20,100	189	15,500
1932	181	61,000	288	36,700
1937	229	90,400	299	38,700
1942	279	197,400	348	70,000
1943	280	238,800	344	75,500

Aims. The junior college aims to meet a variety of higher educational needs of the community in which it is located. Economy is one of the community needs which the publicly controlled institution meets; the student can attend a local college and continue to live at home. Other needs include preparation for advanced work in the case of students who transfer to a senior college or university; general education for those planning to terminate their formal education at the junior college level; specialized preparation for particular occupations, especially of the semiprofessional type; and appropriate courses, both cultural and vocational, for adults in the community. Recent studies have shown that three-quarters of the students who enter junior colleges do not continue their formal education in any other educational institution. For this reason more and more stress is being devoted to so-called terminal education, whereas in the earlier years of the junior college movement chief stress was placed in most institutions on the transfer function.

Curricula. For the student planning to continue his study for the baccalaureate or higher degrees the junior college usually offers courses which tend to parallel closely the courses in arts and sciences given in neighboring universities. To the student who plans to complete his or her formal education at the sophomore level the junior college offers two years of general education, frequently including a number of courses of the survey type, designed especially to prepare for good citizenship and for broad social understanding through curricula that emphasize breadth, unity, and comprehension.

The junior college offers a unique opportunity for training in the group of semipro-

fessional fields. There is a considerable group of occupations between the level of the trades and the level of the professions, commonly designated as semiprofessions, for which two years of college education are considered necessary and sufficient. In engineering, for example, a careful analysis of actual practice has shown the existence of at least three positions on the semiprofessional level for each one on the graduate level. Among the semiprofessional curricula offered in junior colleges are accounting, agriculture, aviation, banking clerkship, business administration, commercial art, dental assistantship, engineering technology, finance, forestry, home administration, hotel management, medical secretaryship, merchandising, nursing, police work, recreational leadership, and secretarial work. The larger California junior colleges, like Los Angeles, Pasadena, Modesto, San Jose, and San Francisco, offer 20 to 30 such semiprofessional curricula.

Successful completion of any junior college curriculum is increasingly being marked by the distinctive junior college degree or title of Associate—usually the Associate in Arts; less frequently the Associate in Science, Education, Home Economics, Engineering, Secretarial Science, or Music. More than 120,000 Associate's degrees or titles have been conferred by 250 junior colleges in the past 25 years.

Current statistics. The *Junior College Directory 1943* lists 624 junior colleges in 45 states, with 14,000 faculty members and enrollments totaling 314,000 regular and special students. About 7 per cent are of the four-year type mentioned above, the two-year institution being the prevailing type. With the exception of three institutions for men, all of the publicly controlled junior colleges are coeducational. Of the privately controlled group, 39 are for men, 111 for women, and 195 coeducational. Three-fifths of the privately controlled institutions are operated under denominational auspices, the Catholics leading with 48; followed by Baptists, 39; Methodists, 38; Presbyterians, 20; Lutherans, 16; and 15 other denominational groups with one to five each, 33. Twenty-six of the institutions are Negro junior colleges. All except three of these are privately controlled. There is one junior college for Indian students.

About one-fourth of the junior colleges are

JUNIOR HIGH SCHOOL

small institutions with enrollments of less than 100 students. On the other hand, 59 report enrollments of more than 1,000 students. The largest enrollment of regular students is found at Los Angeles City College, with 8,992. The largest total enrollment is 25,152 at Sacramento Junior College, California, but over 22,000 of these are special students who carry an unusually extensive program of adult education. Average enrollments in publicly controlled junior colleges have increased since 1930 from 240 to 872, in privately controlled institutions from 115 to 223.

Of the entire group of 624 institutions, 90 per cent are approved by some recognized accrediting agency—national, regional, or state.

Further information. The American Association of Junior Colleges, organized in 1920, maintains a central office and staff at Washington, D.C., which is prepared to give additional information on all phases of the junior college movement. It publishes the monthly *Junior College Journal*; the annual *Junior College Directory*; and numerous books, monographs, and pamphlets, many of which deal especially with Junior college terminal education. A complete annotated bibliography of 1,600 titles published prior to 1930 was published by the United States Office of Education as *Bulletin No. 2, 1930* (167 pages). Supplementary to this early bibliography, the monthly numbers of the *Junior College Journal* since 1930 have included more than 3,100 annotated references to all significant publications aside from the several hundred articles appearing in the *Journal* itself. An extensive recent reference work containing detailed information on 494 accredited junior colleges and much supplementary information is *American Junior Colleges*, American Council on Education, Washington, D.C., 1940, 585 pages. *The Literature of Junior College Terminal Education*, published in 1940 by the American Association of Junior Colleges, contains more than 1,400 annotated titles in this important field.

W.C.E.

JUNIOR HIGH SCHOOL. Dean Harold Benjamin aptly summarizes the growth and development of the junior high school in these words: "Although the junior high school idea is somewhat old and the institu-

tion itself is relatively young, the latter has aged more rapidly than the former".

During the latter part of the 19th century prominent educators suggested that secondary education begin earlier than the ninth grade. The European tendency of differentiating between elementary and secondary education at about age 12 was originally cited as a reason. The large school mortality in this country at the end of the eighth grade was later regarded as a strong argument.

In 1888 President Charles W. Eliot of Harvard University questioned the effectiveness of an eight-year elementary and four-year high school. In 1892 the Committee of Ten (*q.v.*) recommended that the secondary school period begin two years earlier, leaving six rather than eight years for the elementary school. In 1899 and again in 1907, 1908, 1909, and 1913, similar reports emanated from national committees interested in secondary education.

Most of those active in the promotion of this idea represented institutions of higher learning. Their interest naturally centered in a more thorough knowledge of the academic subjects. It is safe, therefore, to generalize the motives which dominated the junior high school idea in its early stages by saying that it was an interest in the attainment of a higher degree of scholarship rather than a desire either to provide more effective growth for the young adolescent or promote a better society in which to live. Those moulding our educational destiny were still apt to measure school growth in this country by the European pattern.

A second motive, however, was later introduced. During the first and second decades of this century a number of studies of pupil elimination from school were made. These pointed to a large mortality during grades 7, 8, and 9. This fact suggested that these grades did not offer enough of interest to the early adolescent to challenge his ability. Need for a different kind of school was the natural conclusion.

The junior high school idea was therefore evolving through a whole generation of time before the institution was established. As an institution it started almost simultaneously in different sections of the country: in 1910 at Berkeley, California, and the same year in Columbus, Ohio; in 1911 in Los Angeles, California as well as in Easton, Massachu-

setts; and then in succeeding years at St. Louis, Mo., Rochester, N. Y., and Philadelphia, Pa. With this beginning the junior high school movement spread rapidly.

By 1940, a generation after its beginning, the movement had reached almost every community in the country. Approximately 2000 schools enrolling more than 1.6 million pupils are reported in the survey of the U.S. Office of Education in that year.

The 6—3—3 organization (six years of elementary school, three years of junior high school, three years of senior high school) is by far the most common. A great variety of other organizations, however, also exist: 6—6, 6—4—2, 6—2—4, 7—2—3 and 5—3—4. This indicates that the junior high school usually begins in the seventh grade, although in some communities the eighth and in a few cases the sixth grade is a beginning point. (See EDUCATIONAL LADDER.)

The aim of the junior high school is variously stated by different writers. The aims can be summarized under three purposes:

1. To satisfy pupil interest and declared needs through larger pupil activity.
2. To aid pupils in exploring areas of contemporary living to make possible a wise selection among future choices.
3. To develop qualities of good citizenship by encouraging pupils to play a larger part in the life of the school community.

At the conclusion of thirty years of rapid rise in number of buildings, money invested, and pupils attending, educators are beginning to question the extent to which the junior high school has succeeded in carrying out these aims. Caught between an elementary school which emphasized drill in the three R's when the junior high school came into existence and a senior high school which concerned itself primarily with preparation for college, it could not or would not be its own doctor. Algebra and foreign languages were forced down from above; grammar as an aid to English expression, formal geography, and often elementary school methods persisted from below.

The world outside also changed enormously. Neither World War I nor the depression of the thirties existed when the junior high school purposes and curriculum became crystallized. Jobs for younger 'teen age boys and girls were plentiful. Vocational explora-

tion at age 12, 13, and 14 seemed fitting. This is no longer true.

The commercial courses and industrial or shop courses because of their exploratory or prevocational emphasis now seem, to many educators, to be misplaced. The large emphasis on vocational guidance implied in its aims is now less valid.

The progressive elementary school, developed in the last few decades, suggests a very different approach to learning from the emphasis either on drill in the 3 R's or on an organized body of facts contained in geography, history, and the like; at the other end, such experiments as the Eight Year Study of the Progressive Education Association (*q.v.*) and various changes in emphasis taking place in college relieve the pressure to prepare boys and girls in the subjects which they may be called upon to study in senior high school or college.

The junior high school is, however, largely unaffected by these later changes in the schools which flank it. It has developed courses in general science, general mathematics, and general language, supposedly adapted to the level of the early adolescent. It has also provided an extensive shop and household arts program. But these are largely revised subject matter courses. They did not as a rule grow out of a study of the needs of early 'teen age boys and girls as do some of our recent college revisions nor were they gauged to the expressive, creative, and manipulative nature of this age level as is true in the modern elementary school.

The junior high school is also much concerned, at least in theory, with vocational guidance, in spite of the fact that increasingly educators are encouraging the extension of the program of general education through the ninth and tenth grades, thus placing the necessity for vocational guidance beyond the scope of the junior high school.

This school came into existence at a time when the world was passing through the initial stages of a revolution which is affecting all of the existing institutions. It grew rapidly in its physical proportions. It has failed to grow much, however, in its internal structure. It is this lag which gives pertinence to the quotation at the beginning of this discussion, namely, that the junior high

JUNIOR RED CROSS — JUVENILE COURTS

school idea has aged less rapidly than the junior high school as an institution.

There is evidence at present that basic internal changes are likely to appear before long. Already a few schools in different parts of the country are experimenting with various kinds of integrated, unified, and other experience-centered curriculums as opposed to the subject-centered curriculum. If these changes develop as rapidly as seems possible in the light of a body of experimental evidence now at hand dealing with the young adolescent, the junior high school of tomorrow will be very different in curriculum and perhaps in organization from the school of today. (See CURRICULUM, SECONDARY EDUCATION.) J.B.

JUNIOR RED CROSS—See AMERICAN RED CROSS, EDUCATIONAL WORK OF.

JUVENILE AND DOMESTIC RELATIONS COURTS. Underlying juvenile court legislation is the broad principle that the child who comes before the state is to be regarded as a ward of the state and that he is to be saved to the state rather than to be prosecuted by the state. Emphasis is placed on the discovery of those basic needs of the child which are the real causes of his appearance in court rather than the specific act or condition immediately responsible for court action.

According to standards established by U.S. Children's Bureau, juvenile courts should have broad jurisdiction embracing all classes of cases in which a child whose age is eighteen years or under is in need of the protection of the state. The tendency today is to define standards in terms of services and personnel rather than of court organization, since the procedures of these agencies are deemed more essential than their structural form. To assure

effective operation of juvenile courts, the following requirements are regarded as necessary: (1) special and qualified judges and referees with sympathetic understanding of children and family life; (2) probation officers appointed on a merit basis and qualified by education, special training and personality; (3) competent clerical aides; (4) facilities for physical and psychiatric study of individuals; and (5) adequate systems of social and financial records.

In the practices of the best juvenile courts, the hearings are always private and without jury; and the procedure is informal. The detention of the child is kept at a minimum, and always apart from adult offenders. The purpose of the court is to adjust the difficult or neglected child to family and community life by a process of individualized treatment carried on by the judges and probation officers with the aid of social agencies and civic forces in the community. Dependent, neglected, and delinquent children come under the jurisdiction of juvenile courts.

While all but two of the states in the U.S.A. have made legislative provisions for juvenile courts, in practice great variation is found in jurisdiction, organization, and administration. Generally, however, the standards are being raised and the services extended. In June 1938, Congress enacted the Federal Juvenile Delinquency Act which embodies many of the recommendations made by the U.S. Children's Bureau. This bill tends to equalize the treatment of one class of juvenile state wards.

Early in the juvenile court movement, it became apparent that in many situations the court could not deal effectively without exercising jurisdiction over parents and other adults. In 1910, the first Domestic Relations Court was established. This court is a child and family court dealing with problems of both children and families. This combination of all family problems in one court is seen as a natural development in line with modern social work thought. Not all of the states have yet authorized domestic relations courts. (See JUVENILE DELINQUENTS.) M.S.Q.

JUVENILE DELINQUENTS. Children eighteen years old and under whose anti-social acts have brought them in conflict with society to such an extent that they have been adjudged delinquent by some Juvenile Court are called juvenile delinquents. Many studies of juvenile delinquents tend to show that they are the product of environmental influences upon individuals with certain characteristics. Both environmental and personal factors work together to produce delinquent individuals.

Observations and tests show that delinquents differ from normal children mainly in their emotional reaction. They are often emotionally unstable and emotionally immature. Their reactions to discipline and strain are like those of small children, their interests are unusually childish, and they strongly crave excitement and change. These characteristics are themselves affected by the children's early environment.

All people have certain fundamental needs or desires which must receive some degree of satisfaction if their personalities are to become socially well-adjusted. Some studies show that delinquents tend to have especially strong desires. These needs or desires are for affection, status, success, new experiences, increased self direction, and feelings of worthy selfhood. If the home, the school and the community do not offer children opportunities for satisfying these fundamental wishes constructively, then the frustrations and deprivations result in keen dissatisfaction. Some activity must offset this inner conflict and delinquency offers one of the possibilities.

This unhappy, thwarted condition of an already emotionally unstable child may need only the opportunities afforded by a poor environment to lead him to find outlet in delinquent behavior. Acceptance by a gang as its most fearless and ingenious leader may compensate to some extent for his rejection at home, his lack of status at school and in the community. The low moral standard and physical condition of the home, the rigid curricula and discipline at school, and in-

adequate opportunities for worthwhile activities in the community are outstanding factors found to contribute to juvenile delinquency.

Any improvements which relieve these conditions serve to decrease delinquency. Detecting the pre-delinquent early and training him in acceptable forms of emotional expression is a far more hopeful social program than curing the delinquent whose anti-social attitudes, interests, and ambitions have already become his mode of life. (See JUVENILE AND DOMESTIC RELATIONS COURTS.)

The most promising development in the treatment of juvenile delinquents has been the increased use of the case study (*q.v.*) approach with its emphasis on the need for understanding the individual child and the psychological, physical, sociological, and other factors which have contributed to his delinquency. This interest in the causes of juvenile delinquency has encouraged many-sided attempts at correcting the conditions out of which delinquency arises. The desire to prevent the development of juvenile delinquency has often helped secure public support for such different reforms as the adjustment of the curriculum to meet the needs of individual students, the extension of child guidance facilities, the improvement of recreational facilities after school hours, and the improvement of housing conditions.

The segregation of juvenile delinquents from older criminals is prompted by more than the desire to spare the child the shame of being stigmatized as a criminal. Since the juvenile delinquent is usually the child who has already demonstrated his inability to adjust to the environment, calling him a young criminal and letting him regard himself as a criminal may strengthen his asocial tendencies. Largely for this reason, the juvenile delinquent is often treated as a child with a problem, rather than as an offender. Placing him on probation assures careful supervision—when the number of trained probation officers is adequate—without the added complication to readjustment that commitment to an institution so often presents. When a study of the case indicates that removal from his present environment is necessary, the juvenile delinquent is usually committed to an institution that does not resemble the usual prison, or he is placed in a foster home.

JUVENILE DELINQUENTS

There is, in the United States, considerable variation among communities in the treatment of the juvenile delinquent. In some states, all offenders below a given age are treated as juvenile delinquents regardless of the nature of their offense; in other states, any person who commits a serious offense, for example, murder, is treated as a criminal regardless of his age. There are, too, a number of communities where the facilities for studying and treating juvenile delinquents are

so inadequate that there is a wide gap between current professional thinking about juvenile delinquents and the actual practices in these communities. M.S.Q.

K

KALAMAZOO CASE. The second half of the 19th century witnessed a great struggle as to the constitutionality of taxation for the support of high schools. Settled as early as 1819 in Massachusetts, the question arose frequently in the West during this period; of these late 19th century cases the Kalamazoo Case, *Stuart v. School District No. 1 of Kalamazoo*, 30 Mich. 69 (1874) was one of the most influential and was widely used as a judicial and legislative precedent.

Decided by one of the most distinguished of American judges, Thomas Cooley, the case arose as a friendly suit to restrain the collection of such portion of the school taxes as was voted to support the village high school. The issue revolved about the fact that the statute did not expressly provide for a publicly supported high school. Specifically rejecting arguments that such public instruction was invalid as not being practical, or as intended only for a few, Justice Cooley found a "general State policy . . . in the direction of free schools in which education, and at their option the elements of classical education, might be brought within the reach of all the children of the state." (See SUPPORT OF EDUCATION.)

KELLOGG FOUNDATION—See FOUNDATIONS, PHILANTHROPIC.

KERSCHENSTEINER, GEORG (1854-1932). Kerschesteiner was the outstanding German educator of his time. The first period of his career was spent as an elementary school teacher, but growing dissatisfied with the type of formal training he received, and feeling deeply his lack of real understanding, he studied mathematics at the University of Munich and became a successful teacher and educator at a *Gymnasium*. In 1895, when he

was named head of the Munich school system, he was confronted with two practical problems: the reconstruction of the elementary school curriculum and the reorganization of the education of adolescent workers of an industrialized nation. He solved both in opposition to the intellectualism of the Herbartians and in agreement with the principles of Pestalozzi. (See HERBART; PESTALOZZI.) His solution of the second problem was to transform the intellectualistic continuation school into a vocational school. In justification of his work he formed his theory of education, the formulation and exposition of which occupied him from 1929—when he resigned his post in the Munich school system and became professor of education at the University of Munich—to the time of his death. Under the influence of classical German philosophy and its interpretation by Windelband and Rickert, and increasingly of the Dilthey-school, particularly Eduard Spranger, he systematized his *Theorie der Bildung* (theory of education).

Kerschesteiner distinguishes three aspects of *Bildung*: the axiological, the psychological, and the teleological. *Bildung* is never general, encyclopaedic; it is always personal. It demands of everyone that he embody in his individual form (*Gestalt*) the absolute ideas of the good, the true, the beautiful, and the holy, thus promoting in collaboration with his fellow men the harmonious realm of God on earth. From this follows the second, the psychological aspect, that describes the way in which the spontaneous force of the individual strives to an ever better and ever more conscious integration, i.e., his personal structure, his *Wertgestalt*. This process of development is organic, not mechanistic formal training. However, the striving is aimless if the third, the teleological, aspect is neglected. Only in contact with man-made objective culture (*Kulturgut*) can we find our personal interest, our real vocation in this world. Only that part of culture becomes

KINDERGARTEN

meaningful and educative (*Bildungsgut*) to us which strikes a responsive chord in our growing personality. According to this "basic axiom of the educative process," *Bildung* becomes identical with our vocation, which is not just a job but the fulfillment of our life. In humanizing our vocation we humanize the community, the state in which we work, making it more and more a symbol of the eternal values. Critics of Kerschensteiner question whether such an ideal harmony of job and vocation is ever possible in our civilization.

In applying this concept of *Bildung* we understand three conclusions: First, education is civic (*staatsbuergerlich*). As a symbol of the highest values the state is *Kulturstaat*, the cultural norm; that is, it is the aim and, even in its imperfect realization, the master of education. The way that leads to that aim is vocational education. Secondly, the form of education is the activity school (*Arbeitschule*). This means planned and cooperative activity of responsible and devoted individuals striving under the guidance of the teacher for the final perfection of each task. This activity is not play, nor does it furnish egotistical satisfaction or meaningless formal training. Thirdly, the school is unified. It differentiates on the secondary level according to the idealistically conceived differentiation of vocations, so that all human types may find themselves. Kerschensteiner complained constantly that the technical *Gymnasium*, one of the most needed of all *Gymnasien*, was still missing in the German school system.

Kerschensteiner's practical suggestions show strongly the influences of John Dewey and the democratic Anglo-Saxon school tradition; but his theory follows, in the main, Pestalozzi, Goethe, and German idealistic philosophy. It could not be otherwise. He postulated a static ideal democracy, as there has never been a real dynamic democracy in Germany.

KINDERGARTEN. The kindergarten is a type of school founded by Froebel (*q.v.*) in Germany in 1840 but is now a name commonly used to designate any school for children between four and six years of age.

The Froebelian kindergarten was a radical departure from the school procedure of 1840, where instruction was formal and conducted by rote. It introduced excursions, stories, games, and handwork. It recognized play as the child's way of learning about himself and the world.

The subject matter of the Froebelian kindergarten is presented in Froebel's book *Mutter und Kose Lieder*, which contains a series of plays for children. For the mother and teacher there is a statement of the truths underlying each game. The compilation was an outgrowth of Froebel's observation of mothers with their children, and the plays were chosen for their lessons of social or spiritual significance (e.g., family love, unity, dignity, interdependence of labor, and the visible effects of invisible power). In these plays emphasis is laid upon the excursion as a point of departure for all instruction. Interpretation follows through song, game, and story.

Froebel devised a series of educational playthings that embodied his belief that everything in nature symbolizes either unity or diversity or the reconciliation of the two. These playthings, or *gifts* as they were called, consisted of solids, planes, lines, and dots and were presented in that order. The sphere symbolized unity, the cube diversity, and the cylinder the mediation of the two. From these were derived all other forms. Froebel believed that the child could get an inkling of this (although he could not formulate it) through handling these symbolic forms.

The children sat or played games in a circle, for this form symbolized the social pattern. Each child was different from the other, but each was necessary to complete the whole.

The first kindergarten in the United States was a private school. It was established in 1855 at Waterloo, Wisconsin, by Mrs. Carl Schurz for her own children. Philanthropically minded people saw the value of the program for children living in the thickly settled sections of big cities and kindergartens of this

sort were established by private groups, churches, missions and social settlements.

In 1873 the first United States public school kindergarten was opened in St. Louis, Missouri. In 1891 a resolution was passed by the National Educational Association that the kindergarten be recommended as part of all school systems. At the present time several states give full state aid for kindergartens, some have permissive legislation, but some make no budgetary provision for them. In such states the public kindergartens are financed entirely by the local boards of Education.

Teacher training has been part of the kindergarten program since the beginning. At first it was given by private individuals—in a six months course. This was later extended to two years. The state normal schools offered two year courses in kindergarten training as the public school kindergartens increased. This was extended to four years when the normal schools became teachers' colleges.

In 1892 the kindergarten teachers organized the International Kindergarten Union. With membership extended to primary and nursery school teachers the name was changed in 1930 to *Association for Childhood Education*. The association has headquarters in Washington, maintains an office and paid staff, and publishes a monthly magazine: *Childhood Education*.

With changing concepts of child development, of growth, and of educational procedures, the kindergarten in the United States has changed its form. New, larger, and more varied materials have taken the place of the *gifts*. The subject matter has changed to meet present day needs, and the symbolic and metaphysical approach has been abandoned for a realistic one. Freedom of expression and movement, development of self-reliance, and use of excursions, stories, songs, handwork, dramatization and parent education remain.

The beginning of the 20th century saw a growing tendency toward unifying the aims and practices of the kindergarten and those of the primary grades, as exemplified in the introduction of kindergarten-extension classes. The establishment of kindergarten-primary teacher training courses facilitated the introduction of the basic principles of

kindergarten education into the primary grades. Recent investigations tend to show that children who have attended kindergarten exhibit superior development of social traits in later years; make better progress in reading, and arithmetic; and are generally less retarded in the grades than non-kindergarten trained children.

The trend today is to speak in terms of early childhood education—which begins at birth and extends to adolescence, rather than to think of such distinct schools as the nursery school, the kindergarten, the primary grades, and the grammar school. (See also KINDERGARTEN EXTENSION.) J.N.H.

KINDERGARTEN EXTENSION. The extension of kindergarten aims and practices to modify procedures in the primary grades and to mold those of the nursery school was a significant movement of the first third of the 20th century. Beginning in 1873 the publicly supported kindergarten (*q.v.*) in America was gradually established in many cities as an institution quite separate from the existing elementary school. Until the close of the 19th century, the majority of kindergartens were formal institutions adhering to the more symbolic and mystical aspects of Froebelian doctrine. (See FROEBEL.) By the turn of the century progressive elements, supported by the youthful child-study movement, were beginning to make their influence felt. They stressed the principles that education is a process of development rather than one of instruction, that play is the natural means of development for young children, that creative activity is essential, and that the child's present needs and interests rather than future needs should determine the choice of methods and materials.

Primary teachers observed in the kindergarten new attitudes toward children, new activities, methods and materials. Gradually these new ideals and procedures were adopted by first-grade teachers and to a lesser extent by teachers of grades two, three, and even higher grades. In some school systems this trend led to the formation of *kindergarten extension classes* in which kindergarten teachers stayed with their pupils for an extra year and thus taught in the first grade as well as in the kindergarten; in other school systems, the influence of the kindergarten found expression in the modified practices of the regular primary grades teachers. Music and rhythmic activities, drawing, story-telling, games, dramatic play, construction with blocks and other materials, and nature study were among the contributions of the kindergarten to the primary school. The unification of kindergarten and primary education was promoted by leading educators, teacher training institutions, supervisors, and professional organizations during the first four decades of

the present century.

The nursery school (*q.v.*) represents an extension of the kindergarten to provide an educational environment and guidance for children from two to four or five years of age. From the beginning, the ideals of the nursery school have been like those of the kindergarten, and nursery schools have appropriated such materials and practices of the kindergarten as have been found suitable for younger children.

LAND GRANT COLLEGES. During the third and fourth decades of the 19th century there developed in the United States a rising interest in the education of agricultural and mechanical leaders. Resolutions were presented to Congress urging the establishment of colleges of agriculture and mechanical arts. Even before Congress took any action, some of the states, notably Pennsylvania and Michigan, established such colleges. Finally in 1859 a bill sponsored by Senator Justin S. Morrill of Vermont was passed by Congress granting 20,000 acres of public land to each state for each senator and representative the state had in Congress, for the endowment of a college of agriculture and mechanical arts in that state. President Buchanan, however, vetoed the bill because he believed that it would interfere with existing colleges in the various states.

In 1861 Senator Morrill introduced a similar bill, except that the grant was raised to 30,000 acres for each senator and representative, and military science and tactics were added to the curriculum. (See MILITARY EDUCATION.) This bill was passed by Congress and signed by President Lincoln in 1862. A total of 11,367,832 acres of public land was given to the states to endow these colleges, and fifty-one states and territories now receive grants from the federal government to help support these schools. Eighteen states added the land grants to the endowment of their existing state universities and added the new work as part of the university. Three of the states gave the grants to private institutions already established within the state, and thirty established new and separate agricultural and mechanical colleges.

Probably no aid for education given by the

federal government to the states has proved so fruitful as have these grants of land (and later of money) to the so-called land grant colleges. Most of these colleges have had a tremendous influence upon the development of their states, and the educational importance of the Morrill Act of 1862, establishing them, cannot be overestimated. E.H.W.

LAND GRANTS. Land grants in education are gifts of land, usually to be sold and the proceeds used for the support of schools and colleges. The term is used most frequently to describe national aid or subsidies in the form of land to local authorities for educational purposes. In our own country, land endowments began in the New England colonies, and were continued by the Federal Government after it was established. In the early days of our national history, the resources of the government consisted more largely of public lands than of money. Until well after the Civil War, educational subsidies by the Federal Government to the states were usually in the form of land.

At the close of the Revolution, there were many conflicting claims to the land lying between the Alleghenies and the Mississippi. To settle these disputes, the Continental Congress proposed that the states cede their claims to the national government and thus create a great national domain of public lands. These lands were surveyed into rectangular townships six miles square, made up of sections one mile square, and offered for sale to settlers. Two large parcels of land on the Ohio were sold to companies, and to help the sale each company was granted one entire township for a college, and the sixteenth section of each township for schools. This action became the basis of the future government land policy.

When Ohio was admitted as the first state, the question arose as to whether the new state could tax the public lands belonging to the Federal Government. To settle this question,

LANGUAGE ARTS

Ohio agreed not to tax the public lands—nor, if sold, would they be taxed for five years after sale—if the Federal Government would give the sixteenth section of each township for the maintenance of schools. This was done, and the policy was continued in the case of every new state admitted thereafter. In fact, with the admission of later states, the grant was raised to two and sometimes four sections of each township. Other types of lands, such as saline and swamp lands, were also granted for the support of schools, and national land grants for the endowment of public education formed the basis of permanent school funds in all the states west of the Alleghenies. The Federal Government over the years has given grants of land totaling about 145,000,000 acres to the states for public schools.

The gifts by Congress to the new states of national lands for the support of public education, although begun as a land-selling proposition, helped to create sentiment for public schools and enabled the states to set up state school systems supported, in part at least, by state school funds. LANGUAGE ARTS. At all levels, communication in speech or writing requires a social and psychological adjustment to people and situations. Language is the child's chief mode of social responsiveness and lends both meaning and continuity to his experiences. It is the function of the program in expression to stimulate the child to share his thoughts and experiences with others in the daily relationships of life in and out of school by helping him to clarify his meaning to himself, select and order his ideas in terms of his purposes and the interests of his audience, and embody them in language precise enough to be understood adequately, with due regard for acceptable standards of usage and for the social amenities associated with the given situation. With growing social and linguistic maturity, the child should develop restraint, sincerity, intellectual honesty, a

sense of responsibility for clarity of presentation, and a feeling of security in solving his language problems.

Beginning with Clapp's *The Function of English in American Life*, research on the curriculum in expression has yielded substantial agreement on the broad program, though emphasis on particular phases, such as minimum essentials or creative writing, varies with the educational philosophy and language status of the school. On the elementary level, speech experiences include conversation; telephoning; discussion; planning and reporting (especially in connection with activity units); recounting personal experiences and other stories—real and imagined; dramatization; explanation, including directions and announcements; reviewing; and speaking to large groups. Experiences in writing, as distinguished from those common to speech and writing, embrace social and simple business letters, creative expression, and the keeping of records in the form of minutes, summaries, logs, diaries, and memoranda, usually in connection with units of work. On the secondary level, the same areas are explored, except that the social and psychological problems are more complex in that they require deeper insight into the interests and motives of the other person; for example, putting a new acquaintance at ease during conversation or persuading dormant club members to attend a rally and pay back dues. Likewise, sincerity must accompany more refined language techniques, especially in effective public discussion, if attempts to arrive at valid conclusions are not to deteriorate into verbal jiu-jitsu. The ultimate objectives are the same for all, but the standards of expectancy and the materials used vary with individual ability and need.

Under the impetus of the publications of the National Council of Teachers of English, the trend toward basing the curriculum in expression squarely on the language needs of life, including school life, of which adolescents are acutely conscious, has been marked even on the secondary level, where the writing of weekly themes and paragraph exercises has been traditional. Mental discipline, purportedly inherent in theme writing, can more richly be achieved in creative expression, in which discipline is self-imposed so that the writer may interpret his thoughts to himself,

release emotional tension into patterned channels, and share the universal aspects of his experience with others. Likewise, the logical organization required of a formal essay written in a quasi-vacuum, without a definite reader in mind, can be supplanted by the functional organization of committee reports, editorials, and reviews. However, sheer inertia, the requirements of regents and college entrance examinations, the poor quality of freshman writing, excessive compartmentalization of subject matter which prevents integration of expression with "content" aspects of unitary problems, and the complexity of skills essential to connected written discourse—all have kept the traditional theme entrenched in the high school.

The creative writing movement, launched in an atmosphere of esoteric mysticism and sentimentality, has been stabilized through psychological analysis of the process and revelation of its similarity to other forms of oral and written expression. As indicated by John T. Fredericks, "Creative expression occurs when a person recognizes the dignity of his experience and imposes on it the discipline of expression in an effort to share it with others." The teacher's chief objectives are to amplify the range and improve the quality of experience and help the pupil to select the right word and suitable form, be it poetry, drama, short story, or informal essay. To evoke creative expression, the teacher requires, not a specialized methodology, but insight into subtle intellectual processes, sympathetic understanding of individual emotional states and moods, ability to distinguish between the pedestrian and newly coalesced phrase, tact in selecting the right moment for constructive criticism, skill in creating classroom conditions conducive to self-revelation, and provision for some form of publication. The issue as to whether the teaching of creative writing should be limited to the talented few depends on whether the criterion of evaluation is the literary quality of the end-product or the opportunity afforded to all children for personality integration, keen observation, lively yet controlled imagination, depersonalized reflection, and the fusion of these activities with the apt word and esthetically satisfying pattern.

Broad methodology may be described in terms of the composition cycle. In his long-

range planning of units, the teacher envisages a hierarchy of aims and enabling objectives and breaks down unitary speaking and writing experiences into their component skills. Language situations, such as inviting another class to witness a play, are then created or allowed to define themselves, so that genuine motives for communication are induced. The period of exploration and organization, conducted individually or in groups, is spent on plans, guide questions, tentative outlines, amenities to be observed, and anticipated difficulties in vocabulary, spelling, and other technical matters. The trial performance or writing period is followed by correction and revision with the advice of teacher and "fellow-craftsmen," so planned as to develop progressive skill at self-criticism. Publication, actual or vicarious, is followed by analysis of reasons for success or failure in terms of audience or reader reaction, comparison with superior specimens culled from student writing, and generalization of a significant principle for later reapplication.

The functional teaching of technical English, including spelling (*q.v.*), embraces the use of technical English both as a positive, integral phase of speaking and writing experiences and as an organized corrective program. Since scientific investigations have failed to show the effectiveness of grammar in the elimination of usage errors, the concepts of grammar are best used to solve practical language problems concerned with relationships among sentence elements in the process of building effective sentences and coherent paragraphs. For example, deeper insight into grammatical concepts and their terminology (which is really an economical form of expression practiced in all crafts) develops with their use to choose the correct case of the pronoun, to condense simple, "safety-first" sentences into complex ones showing relationships more clearly, to secure variety of sentence openings by transposing phrases and clauses, and to combat the sentence fragment or run-on sentence.

What constitutes correctness in English usage must be determined primarily by scholars conversant with linguistic change in accordance with the following criteria: the best practice of able speakers and writers of our day, the recognition of social levels of speech, the validity of geographical varia-

LATIN, TEACHING OF

tions, and the historical development of the language. The corrective program in good usage should be based on an error survey of the school and community, with stress on really serious errors, and individualization of remedial instruction following the administration of standardized and informal diagnostic tests. (See *DIAGNOSIS, EDUCATIONAL*.) In like manner, rules of punctuation and capitalization should be validated by current good usage in the manuals of style of reputable publishers rather than by the arbitrary judgments of 18th century lexicographers. Though the conventional uses of punctuation are best taught through drill, those amenable to rationalization should be approached as a set of symbols, comparable to words, essential to clear, forceful, unambiguous communication of ideas in writing. The corrective program in speech, beyond the simpler problems of voice projection, enunciation of vowel values, and of cognate confusion, should be conducted by speech specialists. (See *ENGLISH, TEACHING OF; SPEECH EDUCATION*.) S.S.

LATIN, TEACHING OF. The ultimate objectives of the study of Latin, as determined by *The Classical Investigation* of 1924 (q.v.), are:

1. Increased understanding of those elements in English that are related to Latin.
2. Increased ability to read, speak, and write English, and increased efficiency in the use of the mother-tongue as an instrument of thinking itself.
3. Increased ability to learn other foreign languages.
4. Development of correct mental habits.
5. Development of an historical and cultural background.
6. Development of right attitudes toward social situations.
7. Development of literary appreciation.
8. Elementary knowledge of the simpler general principles of language structure.

9. Improvement of the literary quality of the pupil's written English.

These ultimate objectives are to be obtained chiefly through the primary objective of the progressive development of power to read and comprehend Latin. But as transfer of these abilities, attitudes, and knowledges is not automatic there must be special training for transfer until it becomes automatic. Each term's work in Latin must be worth while for values contemporaneously realized, and not merely for ultimate values.

In some schools the study of Latin is being crowded out of the curriculum because of its difficulty, its supposed lack of practical value, and the competition with other subjects, but in a large number of our high schools it still has a larger enrollment than any other foreign language.

The teaching of Latin has suffered at the hands of some conservative teachers who are still following old methods. However, great improvement in methods resulted from the work of *The Classical Investigation* (q.v.). Under the newer methods, the transfer of desirable habits, knowledges, and skills from Latin to life situations is consciously fostered and developed. The recent textbooks are attractive in design and appealing in their selection, presentation, and illustration of meaningful subject matter.

The idea, prevalent in some quarters, that Latin is dying out in our high schools is not warranted by the statistics in the reports of the Commissioner of Education. This idea is supported at first glance by the declining percentages, shown in the first column of the table reproduced below, of public high school students who are studying Latin. The number of students in Latin courses, however, has continued to increase, as can be seen from the right-hand column.

Percentages of the High School Population and the Number of Students Studying Latin (1910-34)

	Per Cent	Number
1910	49.05	362,548
1915	37.32	434,925
1922	27.52	593,086
1928	21.99	636,952
1934	16.04	721,320

The apparent discrepancy between the two columns above is explained by the fact that although the number studying Latin has steadily increased, the total high school population has increased much more rapidly. An
